ELECTRIC INCANDESCENT LAMPS are a possible source of danger in gaseous mines or around natural gas wells. Filaments of the lamps glow at very high temperatures, and the breaking of the bulb of a lamp while surrounded with explosive gas instantly brings the gas into violent contact with the filament. The inrush of gas destroys the filament almost invariably, but while it is being destroyed, the gas may become ignited. According to H. H. Clark, of the Bureau of Mines, many tests have been made showing the danger from incandescent lamps. It was observed that the tendency to cause ignition decreased as the lamps decreased in candle-power and increased in voltage. Tungsten-filament lamps are more dangerous than carbon lamps of the same rating. Therefore it is suggested that a reasonably safe lamp is an 8-candle, 220-volt, carbon-filament lamp, with an outer globe of heavy glass, making air-tight inclosures around bulbs, and heavy metal guards, securely fastened to the support of the outer globe. The transmission line and wiring should be carefully attended to.

COAL GAS is usually made from a high volatile coal containing from 35 to 38% of volatile combustible matter. This would analyze as follows: moisture, 2.2%; volatile combustible, 38.1%; fixed carbon, 53.2%; and ash, 6.5%, according to C. C. Tutwiler in the *Journal* of the Franklin Institute. By-products from coal used in gas making in the United States in 1912 amounted to the following:

	Quantity.	Value.
Gas sold, cubic feet	89,693,372,000	$36,681,884
Coke, short tons	12,490,757	48,380,009
Tar, gallons	134,796,438	3,802,017
Ammonia (reduced to NH_3), pounds	51,527,074	4,776,386
Ammonia sulphate, pounds	99,070,777	3,740,075
Ammoniacal liquor, gallons	35,242,549	1,002,807

THE SO-CALLED SOCIALISTIC POLICIES of Australian and New Zealand governments have resulted in the development and operation of coal mines, among many other industries. The New Zealand authorities work two mines in the South Island, and in Victoria a large producer is in full swing, in spite of the many stupid labor troubles, political opposition, and newspaper criticism. In the *Proceedings* of the Australasian Institute of Mining Engineers, containing notes and papers on the May meeting, are five papers on the Victorian coal mine, covering a total of 125 pages. These are as follows: 'Victorian State Coal Mine, Wonthaggi,' notes on development, organization, etc., by the general manager, George H. Broome; 'Geology of the State Coal Mine,' by Stanley Hunter and Leslie Owen; 'Core Drills at the State Coal Mine,' by Stanley Hunter; 'Practical Underground Work at the State Coal Mine,' by John M'Leish; and 'The Electrical Installation at the State Coal Mine,' by Struan S. D. Robertson. The mine is in the Powlett River district, about 60 miles southeast of Melbourne. Six months after it was opened the output was 1000 tons per day, and it now averages about 2000 tons per day, supplying the state railways and other industries. All equipment and working systems are thoroughly modern. To the end of June 1914, a total of £227,142 had been spent on the property; 1,797,708 tons of coal hoisted, worth £809,000; £663,300 paid in wages; and other working expenses, £82,930. There are 508 miners employed, 293 others underground, and 307 on the surface, 1108 in all. Miners average 13s. 9.59d., or $3.29, per shift.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

Delay in Shipping Cyanide from Europe.—The Lead Market and Curtailments of Production.—Copper Exports and Outputs.—Tin.—Richard C. Flower's Activities.—Alaska Gold Mines.

An unfavorable turn in the cyanide situation developed on October 24 when the cables brought news that the tank steamer *Sun* had been taken into Falmouth, England. It will be remembered that after the conference in Washington it was arranged that certain needed goods, among them cyanide, should be brought out of Germany in American vessels. It was at first proposed that the 1000 tons or more of cyanide that was awaiting shipment to this country from Rotterdam, should be brought over on the boat which was sent to bring back dyestuffs. It was impossible to secure cargo space on this, however, and Roessler & Hasslacher attempted to persuade the Holland-American Line to charter an American-owned vessel on which to make the shipment. The Company was afraid to do this, however, fearing interference, and so return cargo space was finally secured on the tank steamer *Sun*, owned by the Sun Oil Co. of Philadelphia, and bound out of that port with a cargo of oil for Amsterdam. The diverting of the steamer, which is American owned, by the British authorities, indicates that they are pursuing their policy of interfering with American shipping whenever there is the slightest ground for the belief that the goods on board may reach Germany. The matter is a serious one to the cyanide operators throughout the country, as the Roessler & Hasslacher plant at Perth Amboy can barely meet the demands of the operators in the United States, and cannot supply any of the Mexican consumption. If it is impossible to bring this shipment through, as planned, the shortage will be seriously felt, and mine-owners ought to make their influence at Washington promptly and vigorously felt, so that they may secure the needed supply of cyanide.

The demand for lead has been slack for a long while, and the low price has caused many of the producers to cut their output to three-fourths of normal. The St. Joseph Lead Co., the largest independent producer, has made such a cut, and, in announcing this, Clinton H. Crane, president of the Company, says that during the past six weeks it has been impossible for the St. Joseph company to sell its lead, even at the low prices prevailing, and that therefore the plant will hereafter be run only five days a week instead of six, and two of the mines will be entirely closed down. The St. Joseph company has also announced that it is going to sever its connection with the American Metal Co., which has heretofore sold the St. Joe lead in New York. Hereafter the St. Joseph company will market its own lead, as the Granby and several other of the producers do. In the Coeur d'Alene district, the Morning mine of the Federal has shut down, and the Stewart Mining Co. has also lowered its output, though the Bunker Hill is still operating at full capacity.

During October, copper exports were surprisingly good, considering all the unfavorable things which developed to affect shipments. Between October 1 and 22, nearly 41,000,000 lb. of copper was exported, and if this rate is maintained for the rest of the month the total exports will be nearly 56,000,000 lb., or approximately two-thirds of the monthly exports just before the war started. So far as is known, none of this copper is reaching Germany, most of the consignments being to England and France, though some still gets through to Holland. Production in this country continues to be curtailed by the closing down of additional properties. The Mason Valley has sent out a notice to its stockholders advising them that the statement of earnings for the quarter ended June 30 will have to be delayed until the present difficulty in marketing copper clears up. Some of the Lake Superior mines continue to operate at full capacity, and the Isle Royale, a subsidiary of the Calumet & Hecla, produced some 600,000 lb. of copper in September, or at the rate of 14 lb. per ton of ore crushed. The output is therefore larger than it was in August, and is still being increased. The Shattuck-Arizona Copper Co. produced 646,713 lb. in September; Utah Copper Co., 6,672,194 lb.; Ray, 3,180,100 lb.; Chino, 2,959,734 lb.; and Nevada Consolidated, 2,718,471 pounds.

The National Conduit & Cable Co. states that at present prices copper should be used more for domestic purposes.

The price of tin has again taken an upward turn on account of the news that a German cruiser had sunk a ship loaded with 850 tons of tin in the Indian Ocean. American producers are giving serious thought to the possibility of tin smelting in the United States, and it is quite possible that some of the many schemes proposed may eventually be carried out. There seems to be every reason to believe that Bolivian tin could be successfully smelted on the Atlantic seaboard at a good profit, and such a venture deserves general support, because if the Bolivian people sold their tin in this country they would be inclined to buy goods from us to take out the credit established.

The Toronto police last week captured Richard C. Flower (who has also gone under the names of Oxford and Montgomery), who many years ago started an interesting career in the way of mine promotion. Before that, he had had varied experiences as a medical practitioner, with a faith cure as a side line. Having benefited Giddeon F. T. Reed, of New York, by some medical treatment, Mr. Reed was persuaded to back Flower in promoting the Illinois Coal & Coke Co., which had a brief existence. About 1900 he floated the Security Milling & Mining Co., with elaborate offices in Wall street and equally fine quarters at the Waldorf. The following year he put out the Arizona Mining Co. and the Lone Pine Co. About the same time he was maintaining the Flower Medical Co., in 34th street, where anybody was treated for anything, and then the grateful patients directed to the offices of the mining companies. In 1903, Theodore Hagerman's wife invested $200,000 in the Eastern Mining & Smelting Co., one of Flower's enterprises, and it was soon rumored that Flower was responsible for Hagerman's death by poisoning. The investigation disclosed his peculiar activities, and though no proof of the poisoning charge could be brought against him, he was indicted for grand larceny. He was placed under $20,000 bail, which he promptly jumped, and has since been a fugitive from justice.

At the Alaska Gold Mines property, the Sheep Creek tunnel is being leveled, and the permanent track laid to the mill. No. 6, 7, 8, and 9 levels have been driven west to the surface, giving an entrance to the mine from the surface of six levels, from No. 5 to 10 inclusive. Recent development has revealed unexpectedly good ore. Construction at the coarse-crushing plant and mill is progressing satisfactorily. The Salmon Creek reservoir has over 110 ft. of water in it, or 40% capacity. By winter it will be 80 per cent.

BOSTON

THE CURB REOPENS FOR BUSINESS.—RESERVE BANKS' INFLUENCE.—THOMAS W. LAWSON.—ELKHORN MINE, MONTANA.—THE FIELDS' PROCESS.—GOLD SHARES TRADED.—UNITED VERDE EXTENSION.

The Boston Curb reopened for daily sessions on October 14, after having remained closed since July 30. About 20 members appeared on the floor, and have been in regular attendance since. There was no excitement, but much interest was manifested in resumption of trading. But little liquidation was in evidence, and there was a noticeable supply of odd-lot buying orders on hand at the opening. Price changes were in the main unimportant as compared with the close on July 30. Lawson specialties, Bay State Gas, and First National were active and fairly strong in price. United Verde Extension and Mexican Metals were freely traded in. The greatest loss sustained by any Curb issue since resumption was that of Nevada-Douglas, which had been selling above $1 previous to July 30, but slumped to 46c., the lowest price in its history. The heavy decline was reported to be due to forced selling by a Boston trader with about 18,000 shares, who was hard hit in the big market. The Curb will not issue the daily 'blue sheets' containing records of sales and quotations until the Stock Exchange opens again.

Considerable interest is attached here to the opening of the federal reserve banks, which will probably be about the middle of November. It is thought that this move will hasten the reopening of the Stock Exchange, and will greatly assist in broadening the loan market on the better class of mining stocks.

Thomas W. Lawson is still absent at the ranch of his son-in-law, Mr. McCall, in Crook county, Oregon, but is expected home before the November election, to take part in the campaign of his friend and connection by marriage, Samuel W. McCall, who is the Republican candidate for governor.

W. R. Allen, former lieutenant governor of Montana, is still in Boston in the interest of the Boston & Montana Development Co., of which he is president. He says the adit at the Elkhorn property in Beaverhead county is being driven at a good rate, and that it is in over 900 ft. Walter Harvey Weed made an examination of the Elkhorn property sometime ago, and submitted a favorable report. Notwithstanding the stringency of the money market, arrangements have been made to continue driving for months ahead. London interests, headed by Sir Robert W. Perks and the London & Midland bank, are stated as still ready to go ahead with the flotation of the issue of $3,000,000 bonds to cover the building of the Southern Montana railroad by McArthur Bros. & Perks interests, railroad contractors.

Makeever Bros., mine operators, express great satisfaction at the progress made with the Fields' process at their Royal Basin property in Granite county, Montana, both on the ores of that mine, and of their El Favor property in Mexico. The reopening of El Favor awaits the settlement of the controversy between the Carranza and Villa factions, this mine having been interfered with in its operations probably more than any other in Mexico, despite its strong fortifications. When El Favor is again active, the Makeevers expect to install the Fields' process there. It now appears likely that these interests will exploit the Fields' process on the market.

More than one Boston house has had salesmen on the road since the Stock Exchange closed, specializing in gold mining stocks. Timely arguments are used about the stability of gold mine earnings as compared with those of copper and silver mines, the present and future need of the world for gold as the result of the European war, etc. The times change and the market changes with them.

The Douglas and Tener interests have formed an underwriting syndicate which has guaranteed the sale of 50,000 shares of United Verde Extension Co. stock at $1 per share. Stockholders are now being circularized to this effect. The prospects of making a mine of this property, which adjoins the famous United Verde owned by W. A. Clark, are now considered brighter than ever. No talk is heard now of litigation with the Clark interests, as was the case about two years ago. The Douglas people have always proved to be such peaceable and friendly neighbors in Bisbee and Cananea, that it is felt that there is not likely to be any trouble in Jerome, notwithstanding the feeling which has existed there so long to the effect that Clark had preëmpted everything of value in that district.

EL FAVOR PROPERTY OF MAKEEVER BROS., SHOWING WALL TO KEEP OUT BANDITS.

HOUGHTON, MICHIGAN

SKILL OF IRON MINERS RECOGNIZED.—MINING TAXES.—THE LATE HARRY ROBERTS OF DULUTH.

That the ability of the Lake Superior iron miners is recognized throughout the country, is shown by the visit to Negaunee of an Eastern contractor seeking mining men. Fifteen experienced miners have left Negaunee, with free transportation and good wages, for Lyon Mountain, New York, where they will be employed at shaft-sinking for the Chateaugey company.

It is probable that the State Tax Commission will be requested to review the 1914 assessments in Houghton county. It is reported that several mining companies are prepared to present complaints to the Commission.

The funeral services of Harry Roberts, of Duluth, former mining expert and operator, were held in Houghton, October 22. Mr. Roberts was a man with wide experience in mining on the Michigan and Minnesota iron ranges. Coming from the tin mines of Cornwall when a youth, he engaged in mining in the East and then entered the employ of the late Joseph Sellwood, then opening the iron mines of Michigan. After working in the Jackson mines at Negaunee, he later aided in the opening of the Colby mine on the Gogebic range, opened the Chandler mine at Ely on the Vermilion range, and the McKinley mine at Biwabik on the Mesabi. With Mr. Sellwood, he opened and operated several other mining properties on the Gogebic and Minnesota ranges. During the past few years he was associated with the Roberts-Kingston Contracting Co. of Virginia, Minnesota.

A general impression prevails here that several mines will have to suspend operations soon or make a further cut in wages. Some managers contemplate getting their men together and talking over the situation and asking them for their opinion as to further action.

DEADWOOD, SOUTH DAKOTA

DETAILS OF THE WILL OF THE LATE T. J. GRIER, AND THE HOMESTAKE'S NEW MANAGER.

That T. J. Grier, the late superintendent of the Homestake, was a provident man, is disclosed by his will, which has been filed for probate in the courts of Lawrence county. The testament bequeaths an estate valued at $243,623. The figures are based on an appraisal by Mr. Grier on May 19, 1913. The values may be somewhat different at this time. The widow is given the residence on Buckingham road, Los Angeles, and one-third of the residuary estate. Bequests of $1000 each are made to eight brothers and sisters, of whom three have died since the will was drawn. The remaining two-thirds is given to the widow, in trust, for six children, to be divided equally among them when the youngest shall be 25 years of age. The children include two sons and two daughters of Mr. and Mrs. Grier, and a son and daughter of Mrs. Grier by a former marriage. Among the most valuable of the items listed in the will are 50,000 shares in the Wasp No. 2 Mining Co., and shares in the First National Bank of Chicago, First National Bank of Lead, First National Bank of Deadwood, National Park Bank of New York, Bank of Montreal, First National Bank of Boston, $6800 in life insurance, property in Los Angeles, and $12,508 in cash. The schedule does not show ownership of any stock in the Homestake company. It is reported that Mr. Grier never at any time owned any, and he made it a policy to refuse to own any, and thereby to escape any censure regarding possible fluctuations in its value.

R. Blackstone, who, since the death of T. J. Grier, has been in charge of the Homestake properties, is an old and valued employee of the Company. His first engagement with the Homestake began in 1878, when, in the capacity of surveyor, he, as a young man, promptly earned recognition for his ability. Later, as the enterprise expanded, his duties became of greater importance, and he was designated chief engineer. Among the earlier tasks that he completed to entire satisfaction was the construction of the Black Hills & Fort Pierre railroad, a Homestake subsidiary, which connected Lead with the timbered tracts to the south and southeast, from which wood and mining timbers were drawn to supply the rapidly growing mine. Upon the completion of the road, he was placed in charge of it as superintendent. Later he directed the construction of many miles of extensions made necessary in order to reach the virgin timber. He held his position at the head of this road until it was finally sold to the C., B. & Q. railway, which now operates it. Mr. Blackstone was also superintendent, for many years, of the 'north end' properties, which included the Father De Smet, Deadwood-Terra, and Caledonia properties, after they were purchased by the Homestake, and later was appointed assistant superintendent of the great Company. This position he has ably filled for a number of years, and during the past two years has for much of the time acted as superintendent during the absence of Mr. Grier. For years past, an important part of Mr. Blackstone's duties has been the supervising of construction of important improvements. Under his direction the water system, hydro-electric plants, and Recreation hall were built.

TORONTO, ONTARIO

SITUATION AT COBALT.—DOME, SCHUMACHER, LONG LAKE, TOUGH OAKES, BURNSIDE, AND TECK-HUGHES MINES.

The lower prices now obtaining for silver, compared with the previous prices of the present year, and the average for 1913, are sure to result in decreased profits for Cobalt companies. Another unfavorable factor is the decision of the insurance companies to raise the rates for shipments across the Atlantic. The old contract expired September 30, and while the new rates have not been made public, it is understood that they will be about double the old. Although there are about 900 less men employed in the district than at the beginning of the war, conditions are back to normal. The Drummond Fraction, Beaver, and Temiskaming have resumed operations, and the Cobalt Lake company has decided to commence lowering the level of the lake.

The Dome production for August was $90,893 from 20,170 tons of ore. This is an average recovery of $4.50 per ton, and the total operating costs, including development, are said to be well under $3 per ton.

At the Schumacher mine some of the underground workers and practically all of the surface men have been discharged. The owner states, however, that it is his intention to erect a mill in the near future.

The Long Lake gold mine, near Sudbury, which has recently come under new management, is obtaining satisfactory results. The property, which had consistently lost money, is now making a fair profit. Production is being maintained at about $23,000 per month.

At Kirkland Lake, the financial pressure following the war has had the effect of stopping a number of operations.——At the Tough Oakes, the most important property in the camp, all underground work has been suspended, and only the 5-stamp mill is running on dump ore. It is the Company's intention, however, to proceed with the construction of the new mill, which will have a capacity of 100 tons per day. It is stated that the Company has a large amount of money out on call in London, but it is impossible to get any of it.——The Burnside is still tied up in litigation, and no work is being done.——A few months ago a new English company was formed to develop a number of properties, but it has also been forced to stop all work. The Teck-Hughes, which is under option to the Nipissing, is showing up well and is being vigorously developed.

LUNING, NEVADA

WORK AT THE VEMILLA, NEW YORK CANYON, WAGNER-AZURITE, ALAMEDA, AND SHIPPER, LUNING GOLD, LUNING IDAHO, RED BUTTE, ESMERALDA, AND COPPER QUEEN PROPERTIES.

The Vemilla property is starting to ship ore this month, a good road having been built to the property, which lies about 1½ miles northeast of the old Garfield mine, which was a large producer in the early eighties. This property consists of nine claims, on which a 140-ft. adit has been driven on the ore, which averages 55 oz. silver and $9 gold per ton. This ground lies seven miles southeast of Luning.

New York canyon is still being actively developed. Two leases have been let on the Mayflower, owned by T. L. Patrick of Goldfield, and on the West End, controlled by H. B. Lind of Goldfield. This part of the district has the largest developed tonnage of low-grade copper ore, and is anxiously awaiting the opening of the leaching plant to custom ores.

The Wagner-Azurite Copper Co. has closed the leaching plant temporarily, on account of the uncertain conditions of copper at the present time. A meeting of the larger stockholders is to determine on the future policy. It is possible that it will be found necessary to roast the ores, on account of the excess of lime, but this will not increase the expense of making metal very much, on account of the cheap fuel that can be procured from Coaldale, and salt from Sodaville, only 10 miles away. The development in the mine is satisfactory, and the Company has sufficient ore blocked out for many years' run.

The leaching test so far conducted on ores from the Alameda and Shipper properties, has proved that these properties can be worked by this process in a manner that will insure the early erection of a plant on the ground.

An important sale was closed here on October 5, when

Sacramento and Nebraska mining men, represented by M. T. Rowland, formerly a Tonopah operator, secured the property of the Luning Gold Mines Co. under a lease and sale agreement. This property consists of 13 claims about four miles north of Luning, and adjoining the Luning Idaho company's property, which has lately been the scene of much activity. These people will immediately commence operations, and have ample resources for carrying on the work. They propose to treat the ore themselves, and thus save the expense of shipping and smelting.

On the Luning Idaho work has been progressing continuously in the adit, and on October 13 the Company cut the casing of the vein on which the shaft was sunk, and before the end of the month should cross-cut another large body of ore. This will be at a depth of over 150 ft. and near the

PART OF WESTERN NEVADA.

hanging wall of the mineralized zone. This vein is about 70 ft. beyond the 18-ft. vein cut a month or so ago, and if it improves in width and value as did the first vein, it will place the mine in condition for extremely large production. It is reported that the people having made a success of the leaching process, have offered to take an interest in the mine for the erection of a large leaching plant to handle these ores.

The Red Butte Mining Co. of Spokane has financed its Company, and Chris. Smith has just returned from headquarters with the necessary money. This mine is about 12 miles northwest of Luning. The mine yields high-grade lead and silver, and indications are good for a large production.

The Esmeralda Copper Co. is about to resume operations, and the manager, Mr. Jacobs, is now on his way from the East for that purpose. There has been considerable development done on the property.

At the Copper Queen Mining Co.'s claims it is understood that arrangements have just been completed whereby there will be an increased activity in connection with this property.

Robert B. Todd of Los Angeles visited the district last week, and was greatly pleased with the progress made, and the development at the Luning Idaho property. Mr. Todd consummated the sale of the Luning Gold Mines Co. He is interested in claims adjoining this property, which have developed several promising gold and silver veins.

Closing of the Mason Valley company's smelter at Thompson will affect this district somewhat, as it was comparatively near, and ore transport to California or Utah is high.

KALGOORLIE, WESTERN AUSTRALIA

EXPLOSIVES AND CYANIDE SUPPLIES FOR THE MINES.—CONTRACT WORK.—WHIM WELL COPPER MINE.—CORINTHIAN NORTH AND VICTORIOUS MINES.

Owing to the war, there has been some anxiety regarding mine supplies, especially explosives and cyanide, but unless something happens, there will be no serious restriction in output of gold. Explosives on the spot are estimated to be sufficient for six months, and Nobel's Explosives Co., Ltd., Glasgow, has cabled its local agents stating that it will have no difficulty in maintaining full supplies. In an emergency, the De Beers factory at Kimberley, South Africa, can supplement supplies. Regarding cyanide, Bewick, Moreing & Co. have just landed from Singapore a full four months supply for all their mines, and other shipments are en route from England. To conserve explosives, all mines, with three and four years of ore reserves, are temporarily curtailing development work. The regularity of the mail steamers may be upset at any time by the commandeering of the boats by the government for the transport of troops to the seat of war. All the Austrian reservists employed in the mines and on the wood-lines have been escorted to Rottnest island for internment during the war.

After being idle for 68 days, the men have resumed work at the Yuanmi mine, in the Murchison district, on practically the same terms as before, except that the work formerly called 'contract work' is now termed the 'bonus system.' In other words, competent men can increase their wages by extra footage. We are not likely to hear any more regarding the abolition of contract work for some time, as no objection was made at Lancefield, on resumption of work there, and, at the Great Fingall mine, the men themselves voted in favor of the continuation of contract work by a considerable majority.

Owing to Germany being practically the only buyer of copper ore and matte, the Whim Well mine in the northwest, like other copper mines in Australia, has been forced to close down. This mine employed over 300 men, and exported about 10,000 tons of ore per year. The Company has been operating a Murex magnetic plant of an estimated capacity of 200 tons per day. The mine was in bad order and all the old workings had been condemned and forbidden to be operated by the inspector of mines, and only new shallow ground has been worked for some months. Two years ago, H. R. Sleeman, the manager, estimated the ore reserves at 1,000,000 tons of 5% copper, and estimated that, with copper at £70 per ton, a profit of £60,000 per year would be made. Later events reduced this considerably.

Since the mill on the Corinthian North at Southern Cross started crushing, in April, 51,278 tons has been treated, returning £46,875, and, as the oxidized reserves are being rapidly expanded, a No. 8 Krupp ball mill and an Edwards' duplex roaster have been ordered to treat the sulphides. The mine has not fulfilled expectations, and it is doubtful if shareholders will get much benefit from it.

The Associated Northern company's Victorious mine at Ora Banda may have to be closed down, as the shipment of the new suction gas engine, ordered in England, has been delayed by the war. During the past six months the Company has expended £15,479 on development and equipment, of which £6472 has been spent during the past two months. Developments at No. 7 level have proved disappointing, as the oreshoots are short and patchy, and G. M. Roberts, the manager, is beginning to be rather doubtful of the success of the venture.

During August, the Horse-Shoe mill treated 22,884 tons of ore yielding £34,216, with a profit of £1014. The north drift at 2900 ft. shows ore worth £12 15s. per ton.——In September the Ivanhoe mill treated 19,094 tons for £30,700, with £10,790 profit. The main shaft is down 3151 feet.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Chisana

According to an estimate of G. R. Goshaw, the district's gold yield for the season was as follows:

Bonanza creek	$140,000
Little Eldorado	79,000
Big Eldorado	6,000
Skookum	24,000
Gold Run	1,500
Coarse Money	1,000
All others	1,500
Total	$253,000

The sluicing season was less than 90 days. About 125 people will winter there.

Cordova

At the Mother Lode copper mine, the Pittsburg cross-cut has cut the main vein, giving 380 ft. of vertical depth. According to the president, James L. Godfrey, this development proves the extension of the rich chalcocite ore from the surface. Work will be continued during the winter with 40 men, and 1000 tons of ore will be mined and shipped for smelting.

MAIN STREET OF CHISANA IN WINTER GARB.

Fairbanks

Record hoisting was recently done at the claim of C. Watson on the Chatanika flats, when 582 buckets of material was hauled from a depth of 147 ft. in one shift. He employs 19 men, of whom three are Bulgarians, four Swedes, four Russians, three Austrians, two Norwegians, one German, one Californian, and one Scotchman, who are working amicably in spite of the war in Europe.

Juneau

During September the Alaska Treadwell output was as follows: 540 stamps crushed 78,015 tons of ore, yielding $93,196 by amalgamation and $88,444 from cyanidation of 1731 tons of concentrate. The total realizable value was $179,823, and the yield per ton $2.33. Operating expenses totaled $78,778, and construction $19,995, leaving a profit of $81,050. Development in the mine amounted to 618 ft., and the stock of broken ore decreased 48,079 tons.

The Alaska Mexican mill crushed 19,173 tons of ore in September, yielding a total of $14,641 by amalgamation and treatment of 360 tons of concentrate. Net profit was $14,279. Development amounted to 55 ft., and the stock of broken ore decreased 6736 tons.

The Alaska United Ready Bullion and 700-Ft. Claim mills crushed a total of 38,157 tons of ore, yielding $78,314 by amalgamation and treatment of 894 tons of concentrate. There was a profit of $11,024 from the former mill and a loss of $753 from the latter. Development totaled 1283 ft., and the stock of broken ore increased 1288 tons, and decreased 9418 tons in the respective mines.

Ketchikan

The Gold Banner claims, stated in a recent issue of the *Press* as belonging to E. Steers, are owned by Joseph Hamblet.

ARIZONA

At the state fair at Phoenix there will be contests in first-aid and mine-rescue work. There are three entries in each of the contests so far, namely, the Old Dominion of Globe, Detroit of Morenci, and Copper Queen of Bisbee.

Cochise County

At the Shattuck-Arizona mine in September, a good tonnage of high-grade ore was mined in several stopes, but no ore was shipped. There is stored about 150 tons of 40% copper and 30-oz silver ore. Development during the month totaled 998 ft. At 800 ft. there has been opened 121 ft. of ore assaying 4% copper, $2 gold, and 2 oz. silver per ton. The rise above the 900-ft. level is up 96 ft. and shows 9% ore at the top.

Mohave County

The old Tennessee mine at Chloride is shipping about 150 tons of zinc-silver ore per day to the Needles smelter.——The Golconda, at Todd basin, is sending 40 tons of zinc concentrate daily to the same smelter. About 10,000 ft. of work has been done in this mine, in charge of John Boyle. The vein worked averages 4 ft. wide, and 20% zinc, with some gold and silver.——A wide gold-bearing lode is being developed at the Cyclopic.——At the Gold Reed, two miles from the Tom Reed, there is 5½ ft. of ore on the 200-ft. level. The incline shaft is down 220 ft. following a 4-ft. vein. C. R. Walters is manager.

Yavapai County

(Special Correspondence.)—At a depth of 250 ft. in the Humboldt Consolidated mine at McCabe, 12 in. of 400-oz. silver ore has been opened for some distance.——In spite of many difficulties, the new mill of the Dolphin mine on Turkey creek has been finished. W. H. Temme is in charge.——The

first carload of ore from the Poverty mine on Slate creek to the Hayden smelter returned 61 oz. silver, $14 gold, and 10% copper.

Hayden, October 17.

The smelter at Humboldt is employing 145 men, and there are 75 miners at the Blue Bell, according to G. M. Calvocoress, general manager for the Consolidated Arizona Smelting Co. Unless the price of copper falls too low, present conditions will be maintained.——The Arizona Power Co. has closed another contract for 2000 hp. for the United Verde Copper Co.'s new plant at Clarkdale.

YUMA COUNTY

(Special Correspondence.)—Frank B. Keever, of San Francisco, general manager for the Fortuna Mines Corporation, with properties in the Fortuna district, is in Boston in the interest of the old Fortuna mine, formerly owned by the estate of Charles D. Lane. The Fortuna produced nearly $3,000,000 in gold up to about 12 years ago, and paid over $1,000,000 in dividends. Its production was cut short by the intrusion of a fault at the 800-ft. level, and the previous management spent over $400,000 in futile efforts to relocate the Fortuna vein, sinking a winze from the 800 to the 2000-ft. level. The new management has spent about $100,000 more, working along directly opposite lines, after a thorough geological mapping of the property, and has found the vein again. Eugene R. Foss is heavily interested with Mr. Keever in reviving this old property.

Boston, Massachusetts, October 19.

CALIFORNIA

The oil output of the state in September was 289,979 bbl. per day, a decrease of 4000 bbl. compared with August. Shipments from the 11 fields totaled 6,869,910 bbl., and stocks are now 55,027,328 barrels.

AMADOR COUNTY

A dam is being constructed on Amador creek, three miles west from Amador City, to impound tailing from the Original Amador mill. It will be constructed 30 ft. high, and will hold about 1,000,000 tons. T. S. O'Brien, mine superintendent, and Louis S. Cain, engineer, are supervising the work.

During September the Plymouth mill worked 650 hours, crushing 7474 tons of ore, yielding gold worth $33,600, including that in concentrate.

BUTTE COUNTY

The old Coal mine, near Magalia, is being reopened by Portland people, under the management of C. Cramer.——A $140 gold nugget was found recently in the west branch of the Feather river, near Magalia, by E. Burt.——Cleaning out the old Indian Spring adit is being conducted under the direction of E. T. Barnett. Out of over one mile in length, 3000 ft. has been completed.

CALAVERAS COUNTY

(Special Correspondence.)—Fordyce & Co., of Boston, announce the receipt of a telegram from the manager of the Royal Gold Mines property, at Angels, stating that the mine is unwatered down to the 200-ft. level, and that a 4-ft. vein has been cut, from which assays were made of $46 per ton in gold. A claim of 5,000,000 tons of $3 ore which can be mined and treated at $1 per ton has been made for this mine, which has been examined by several American and foreign mining engineers, but it is now claimed, further, that high-grade ground such as the recent development will raise this estimated average. The management expects to begin hoisting ore and operating the first unit of the mill by January 1, 1915.

Boston, Massachusetts, October 19.

ELDORADO COUNTY

A 5-stamp mill is being erected on the old Pacific mine near Placerville by J. H. Santo and P. D. Burtt. Ore will be mined from the 500-ft. level.

INYO COUNTY

Grading for the Bishop Creek 50-ton cyanide plant was finished last week, and the building is now being constructed. It is hoped to have the 10-stamp mill and treatment plant working by the end of the year. To prevent tailing getting into the creek, it will be discharged as dry as possible, and two restraining dams built.

KERN COUNTY

Rich ore has been opened in the Aunt Rosa mine, in the Amalie district. This property is owned by W. P. O'Meara and associates. West of this claim, and also in the Phillips and Crane claim, Hart Bros. has opened good ore. J. Ferris' 70-ton mill should soon be in operation. The camp is eight miles east of Caliente. The formation is schist, lime, and granite.

NEVADA COUNTY

At a depth of 80 ft., there is 24 in. of rich ore in the Dunmaine claim, in the Rough and Ready district. Some good specimens have been found, and the property is likely to be a fair producer.

Good progress is being shown in the additions to the Empire stamp-mill. Rich ore is being mined from the Pennsylvania mine, owned by the Empire company.

PLACER COUNTY

The magnesite deposit being developed five miles from Alta by J. D. Sullivan is said to look promising.

San Francisco men have purchased the Rough and Ready gravel mine, on Dutch Flat, from W. Gray. The concern is known as the Naomi Mining Company.

PLUMAS COUNTY

Improvements are being made to the mill of the Seneca Consolidated company's White Lily mine. J. J. Reilley is superintendent of this and other claims.——A large vein of $20 ore is being opened in the Plumas Bonanza mine, on Winter's creek. M. M. Page is manager.

SHASTA COUNTY

(Special Correspondence.)—There has been a marked revival in gold mining throughout Shasta county since the decrease in copper mining, and several important deals are reported by owners to be under negotiation.——Engineers, said to be representing John Hays Hammond and associates, are examining placer ground in the vicinity of Igo. The properties have been worked in a small way for years, and are considered highly promising. The same people are examining ground along Clear creek, below Redding.——Shipments of high-grade ore from the Uncle Sam mine, eight miles from Kennett, are being made to the Selby smelter. The 10-stamp mill is being overhauled for operation. A strong vein of good ore was recently opened in the property after a long search. Fred Dakin, Jr., is superintendent.——Arthur Rule and associates of Redding are developing a group of promising gold claims near the Uncle Sam, and recently uncovered some good quartz.——Van Ness Bros. are developing their Five Pines group and opening good ore.——James Hulme has a small force at work in the Gold Leaf mine, near Redding, in the interest of Seattle people who are considering the acquisition of the property.

Redding, October 26.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—There have been some good developments made in the mines here lately. The Ruth lease in the Golden Edge mine, which adjoins the Sun and Moon, is in good ore. They have one streak of pure argentite liberally sprinkled with coarse gold.——There has been a good find made in the Big Five tunnel at the intersection of the Lake and Belman veins. There is said to be 3 to 5 ft. of ore which averages about $100 per ton in carload lots. It is one of the

best discoveries made in this district for a long time.——The old Gunnell mine, which is near the terminus of the tunnel, is shipping a considerable quantity of good grade ore.——Central City and Black Hawk are quiet, as practically all of the business for this district is now done through the tunnel.——The Newton mill, which jigs ahead of the stamps, is running almost continuously, and the Roberts or Jackson mill is running spasmodically. Except for these two, and the Argo mill, there is no other work in the custom business.——The Little Mattie mine, on Chicago creek, is operating continuously on low-grade ore, the plant being of the usual type for this district. There is talk of installing cyanide equipment. There is a new cyanide plant on the Oneida, near Freeland, but it has not yet started. Its capacity is 50 tons per day.

Idaho Springs, October 19.

A molybdenite claim of Lively Bros. and W. Young, near Georgetown, has been optioned to the Primos Chemical Co. for $75,000.——The Bard Creek Mining Co. has acquired machinery in the Pay Rock mill, and will move it to Bard creek, where the Company has a large tonnage of ore ready for mining.

Lake County (Leadville)

The Down Town Pumping Co. has let contracts for its pumps to the Providence Engineering Works of Rhode Island, and motors to the General Electric Co. There will be four motor-driven centrifugal pumps of 1500-gal. per minute capacity each, against 450-ft. head, with 300-hp. motors. There are to be three separate sources of power, in case of accident to any one.——Lessees on the Pat Connors lease of the Ibex are shipping more rich gold ore.——Another shift has started at the Big Five company's mine. Eight to twelve-ounce gold ore is being shipped.

In the Twin Lakes district, the Bengal Tiger-Gordon mine is again to be worked, after a lapse of 17 years. There is between 40,000 and 70,000 tons of $10 ore blocked out, as estimated by engineers in 1897, since which time the property has been tied up by litigation.——In this district are the claims at Hartman and Mock, which are yielding 10-oz. gold ore.

In the Lackawanna district, the Lackawanna Belle is proving a good mine, and 3-oz. gold ore has been opened for some distance. A new 1500-ft. adit is contemplated to cut the ore at a depth of 1100 ft.——The Miller mine also shows good ore.——From the Mt. Champion mine the monthly output is about 300 tons.——Lessees at the New Monarch are opening rich ore.

San Miguel County

The output of the Tomboy in September gave a profit of $31,000. An abstract of the annual report appears on another page.

Teller County (Cripple Creek)

It is reported that lessees on the 800-ft. level of the Golden Cycle mine are producing ore worth $16,000 per month. They have a large block of ground.——Plans and specifications have been finished for a 100-ton mill for the Cripple Creek Cyanide Mining & Milling Co., and bids for grading and construction are required. The Company has made contracts for ore treatment from mine operators. Howard Shutz is secretary.——The Gold Coin shaft of the Granite company is to be sunk from 1200 to 1400 ft. depth. Water is being baled from the lower levels for this work, No. 12 having been flooded for several years. Good orebodies are said to exist at this point.

Anderson Bros., lessees in the Dexter mine near Battle mountain, have opened 4 ft. of ore worth $20 and over per ton, for 175 ft.——The Vindicator company is planning extensive development, and has ordered a large Ingersoll-Rand compressor from the Stearns-Rogers company of Denver, and will move a compressor from the Hull City mine to the Vindicator. To drive these machines, a 60-hp. motor has been ordered, being the largest in the district by 150 hp. About 20 motors, aggregating 300 hp., have been ordered for the ore-house, conveyors, and concentrating plant.

SILVER LAKE MILL, NEAR SILVERTON.

IDAHO

Blaine and Custer Counties

The ore deposits in the Sawtooth quadrangle of these counties are discussed by Joseph B. Umpleby in *Bulletin* 580-K of the U. S. Geological Survey. This area is a high, mountainous district with summits at elevations of 9500 to 10,000 ft. above sea-level, and includes the divides between three large drainage basins. The Sawtooth mountains run sinuously across the quadrangle a little north of its centre. From the Salmon river they rise abruptly from a broad valley floor, 7000 ft. high, to 9000 to 10,000 ft. As seen from the north, the crest is very much like unto the teeth of a saw. The area has few trails and fewer roads, and travel is exceedingly difficult in most parts. A trail up Bois river goes to the old camps of Vienna, Sawtooth, and Carrietown. The earliest locations were made in Boulder basin in 1879. Work was active until 1890, but the output of silver-lead and silver ores is estimated at $5,000,000 for the period. Concentrating plants were erected at nearly all the camps to handle poor ores, and a 30-ton lead smelter at Galena. During recent years, only the mill in Boulder basin has been operated. The principal ore deposits are fissure veins and replacements along shear zones. Siderite and quartz are the characteristic gangue minerals of the silver-lead deposits; while the silver ores occur well within the main granite mass. There are a few gold and zinc lodes in the district. All of the mining districts in the quadrangle are described in the work.

Shoshone County

A general idea of the magnitude of the development of non-producing mines or prospects, and the large amount of money being expended in the Coeur d'Alene district in this class of work, is gained from a résumé of the outstanding assessments levied by corporations, according to advice received in Spokane, Washington, from Wallace, Idaho. Fifty-one mining corporations in the vicinity of Wallace have assessments levied, and in the course of payment. The total combined number of shares in these corporations aggregates 64,500,000, while the aggregate capital of these companies amounts to $62,250,000. Of these corporations 18 are capitalized for $1,500,000, 24 at $1,000,000, four at $1,250,000, two at $125,000 and three at $2,000,000. Assessments range from 0.1c. to 3c. per share on the outstanding capital stock. The total amount of money raised by these assessments, assuming that the capital stock of each concern is all issued, would amount to $279,625. It is fair to estimate that at least three-fourths of the capital stock of these corporations is issued and subject to assessments. This would return a net sum of more than $200,000 to the

treasuries of these various corporations for immediate use, in the development and other needs of the properties. Of the total amount paid in on assessments, more than half is paid to miners employed, and the remainder for machinery, tools, provisions, and necessary improvements. There are, without doubt, 200 corporations in the district that are developing their properties by the assessment system, and it is fair to estimate that more than $500,000 is annually collected and expended in the Coeur d'Alene district for the development of its many promising legitimate mining properties.

One foot of shipping and five feet of milling ore have been cut in a rise being driven from the lower adit of the Idora Hill mine, under lease to the Tuscumbia company, to connect with the upper 300-ft. workings of the latter Company.——Over 4000 ft. of work has been done in the Aurora-Sampson mine, near Wallace. The vein is being developed and shows iron ore with some lead and silver.——Development in the Great Eastern company's claims at Mace is very promising.——A 5-ft. vein of quartz and iron, containing lead and silver, is being developed in the Toledo, above Burke.——The district known as Vandetta gulch, above Murray, has attracted considerable attention for a long time. The area is somewhat rough, but heavily timbered. At the Vandetta Chief, Lucky Four, Giant Ledge, and others, a good deal of interesting work is under way.

MISSOURI

Jasper County

The output of the Joplin district during the week ended October 17 was as follows: blende, 7,534,235 lb., averaging $34.27 per ton; lead, 1,365,570 lb., at $39.57 per ton; and calamine, 169,180 lb., at $19.72 per ton. The total for 42 weeks is 397,410,183 lb. blende, 69,359,806 lb. lead, and 25,540,290 lb. calamine, with an aggregate value of $9,517,775. The greatest effect of low ore prices is noted in the heavy producing sheet-ground areas, not only of the Webb City district, which is the heaviest producer of sheet ores, but likewise from Duenweg, Carterville, Prosperity, and Joplin, all of which produce some sheet ore. Few sheet-ground mines can operate profitably at less than $40 per ton, and comparatively few can run at this figure and still make a profit.

The 250-ton concentrating plant moved to the Carter land, north of Webb City, is ready for work.——A mill is being constructed by Short and Carey in Cottonwood Hollow, northwest of Joplin. It will treat ore from a soft formation at 100 ft.——Gas for use under boilers at mines and manufacturing plants was discontinued last week by both the Kansas Natural Gas Co. and the Joplin Gas Co. Consumers were requested to make other arrangements for fuel throughout the winter. For a number of years both Companies have conserved their supplies through the winter months for domestic consumers and for heating purposes.——The 250-ton electrically driven tailing mill of Bendelari and Longacre has been completed at a cost of about $8000, and placed in operation. There is several years' supply of tailing on hand. Equipment consists of two large jigs and five tables, elevators, and other accessory equipment.

MONTANA

Fergus County

During September the Barnes-King mill produced gold worth $23,035.

Granite County

Machinery for the Granite County Power Co.'s plant at Maxville has been sent to the site from the Allis-Chalmers works at Milwaukee, and according to the consulting engineer, Walter Neal, it should be in operation by the beginning of 1915. Current at 6600-volt pressure will be transmitted six miles to the Royal Basin Mining & Milling Co.'s property, where it will drive crushing apparatus and the Field flotation process.

Silverbow County

'Muckie' McDonald, Joe Bradley, and four other disturbers of the peace at Butte refused to plead when charged by the district court last week, so a plea of not guilty was made for them.——Repairs to the Butte & Superior main shaft will take 60 days to complete. The 75c. quarterly dividend will be paid as usual. During September the mill treated 34,850 tons of ore yielding 10,223 tons of zinc concentrate, assaying 53.61%, with 89.69% recovery.——The Bullwhacker Copper Co. is being reorganized, and a meeting of shareholders was held at Phoenix, Arizona, on October 26. The new Company, with a capital of 1,000,000 $1 shares, is called the Butte-Bullwhacker Mining Co., registered in Montana. The old Company was indebted to Clark Bros. & Klein, of Spokane, for $121,000. The mill can be overhauled for about $20,000.

The East Butte company cannot make any profit with copper at between 11 and 12c. per pound, according to the manager, Oscar Rohn.——Save the Butte & Duluth property, all properties east of Butte are idle.

NEVADA

Clark County

The reported rich gold discovery on the old Quo Vadis mine, 23 miles southeast of Las Vegas, amounts to practically nothing, according to Charles D. Wilkinson, manager of the Yellow Tiger company of Goldfield. The prospector had about 20 lb. of rich ore from a 75-ft. adit. On the strength of this the country had been staked for miles around.

Esmeralda County

The pumps for the 1325 and 1750-ft. levels of the Merger mine have arrived at Goldfield. The pump for the former level is a 6½ by 15-in. triplex type, and that for the lower level a 6-in. centrifugal.——The Jumbo Extension net profit in October is expected to be about $75,000. On October 22 the Company paid the balance of $30,000 due to the Merger company for its Velvet claim.——The Talmage Gold Mines Co., operating on Vindicator mountain, northeast of Goldfield, is meeting with encouraging developments under management of C. W. Hays.——Underground work is to be resumed on the Yellow Tiger in a few days.——Lessees at the Vernal have shipped 19½ tons of $60 ore from the 200-ft. level.

The Goldfield Consolidated company reports as follows for September: The mill treated 27,871 tons of ore yielding $120,600 net profit. Lessees produced 1127 tons, worth $20,076, of which the Company received $10,546, less the cost of transport and milling. Mine development totaled 2318 ft. at $6.49 per foot, and nothing of importance was revealed. Costs per ton totaled $6.53 per ton of ore milled.

Humboldt County

A small stamp-mill with amalgamating and concentrating apparatus has been started at the Forvilly Rochester Mining Co.'s mine. It was erected by Cliff De Lorme and F. W. Kittle.

Mineral County

In order to install and connect up new equipment in the Aurora mill, the work will be suspended for about 10 days.

Nye County

At Tonogold, the new gold district near Tonopah, work is still of an interesting character. Saunders and Sorensen opened 24 in. of ore at 15 ft., of which 12 in. assays over $40 per ton. A shaft is to be sunk to 150 ft. Ten inches of $70 to $80 ore is being sacked in the Jarvis-Richard lease. Dougherty, Mooney, and MacNamara are cross-cutting at 50 ft. The joint shaft of these miners and the Jarvis-Richards people is down 30 ft., showing 2 to 5 ft. of $18 ore. Lumber is on the ground to timber the Murphy shaft to 100 ft. A hoist is working at the Campbell & Kelly lease. Kelly and Mullin have 24 in. of $40 ore at 15 ft. depth. Employees of the Montana-Tonopah mine have their Tennessee shaft down

38 ft. J. May is down 35 ft. and is sacking ore. A. Wardle is down 42 ft. At the Miner lease the shaft is 30 ft. deep, and is encouraging. It adjoins the Spencer and May, two of the best claims at Tonogold, according to *The Tonopah Miner*.

Eight mines at Tonopah last week produced 10,473 tons of ore, worth $204,474.——The attachment of the Jim Butler company against the West End company was dissolved on October 23 by Judge Mark R. Averill, who thought that it was unnecessary, inasmuch as an injunction already was in force giving sufficient protection.——Development in the Tonopah company's mines totaled 402 ft. last week. The mill is treating 2675 tons of $16 ore per week, with 92% recovery. ——The net profit of the Extension in September was $62,666 from 5447 tons of ore. Six Wilfley tables have been installed and started. Foundations for 20 stamps are nearly finished. ——In the Belmont, development amounted to 532 ft. last week. A shipment was made of 116,791 oz. of bullion.

NEW MEXICO

Otero County

(Special Correspondence.)—The well known Tiffany turquoise mines at Turquesa have been purchased by Frederick K. Gilbert. The principal supply of the United States is from these deposits. Litigation has retarded development in the past. The gem properties in this state are fully described in U. S. Geological Survey reports.

Turquesa, October 24.

SOUTH DAKOTA

Pennington County

The Rochford-Wyoming Oil Co., at Rochford, has a well down 670 ft., using a Star drill. Oil-bearing sand is expected at about 1500 ft., as two other wells are yielding oil nearby. About $3500 has been spent for labor, tools, casing, etc., during the summer.

The Homestake Mining Co. paid its monthly dividend of 65c. per share on October 26. The total this year and to date is $1,419,600 and $32,546,000 respectively. Shares are quoted at $115.——The Wasp No. 2 company paid 1c. per share, amounting to $5000, on October 15. Shares are quoted at 75c. About 30% of the ore for the mill lately has been mined from a porphyry dike in the southwest part of the open-cut, and yields profitable returns. The new locomotive and cars are proving useful in stripping operations.——Several additions have been made to the mill equipment of the Golden Reward at Deadwood. A tube-mill now grinds the roasted 6-mesh ore, and an L. C. Trent displacement tank and a Moore filter treat the slime.

UTAH

A permanent exhibit of the mining and metallurgical industries of the state is proposed for Salt Lake City, by mining men and manufacturers. One exhibit suggested is a *papier maché* relief plan of all the mining districts, 8 by 9 by 60 ft. in size. There will also be shown cases of minerals. The total cost is estimated at $3000, of which the Commercial Club will give $1000.

Carbon County

The Cameron coal mines, 1½ miles west of Castlegate, have been sold by F. N. Cameron and others, of Salt Lake City, to M. S. Browning and associates of Ogden. The area is 400 acres, and is producing 300 tons of coal per day. This is to be doubled in the near future.

Juab County

Four feet of good lead-silver-gold ore has been opened on the 700-ft. level of the Emerald mine in the Tintic district. J. L. Yundt is manager.——W. Nelson, a lessee on the Yankee Consolidated, has opened 8 to 12-oz. gold and 100-oz. silver ore in an old stope on the 100-ft. level.——The Lower Mammoth and May Day mines are shipping zinc and lead ore, respectively, the latter averaging 45% lead and 45 oz. silver per ton.

Summit County

A suit between the Silver King Coalition and Silver King Consolidated companies, at Park City, was ended last week, when the former deeded two mining claims to the latter, and the latter four claims to the former.——A 12-ton motor armature for the Consolidated was being hauled to the mine by a 26-horse team last week.

WASHINGTON

Feary County

The first payment of $8000 on the Last Chance mine at Republic has been made by the Western Union Mines, which has a bond and lease for $187,500.——The property of the Keller & Indiana Consolidated Mining Co., sold under judg-

MAP OF WASHINGTON.

ment at Republic recently, was bid in by Lester P. Edge, a prominent Spokane attorney, for $1160. Included in the purchase is the Boyle smelter, dam, flume, generating machinery, and other equipment at Keller, erected at a cost of $300,000 by Indiana investors. The mining property, developed by a 2000-ft. adit, is not included in the transaction.

CANADA

Ontario

Bullion shipments from Cobalt for the year to date total 6,385,247 oz., valued at $3,553,192.——Four machine-drills are working on the new 375-ft. level of the Cobalt Lake mine. Two inches of high-grade and four feet of mill ore is developed on the level. Diamond-drilling from No. 4 shaft proved the conglomerate to a depth of 549 ft., which is lower than estimated.——There are 50 men employed at La Rose mine in surface stripping and trenching, on the eastern part of the property.——The Crown Reserve company has declared a dividend of 2%.——The Trethewey mine produced 40,000 oz. of silver from 2800 tons of ore in September.——At the Temiskaming the main shaft is down 768 ft., and high-grade ore was cut at 750 ft. Six drills are working. The Company's cash balance on September 30 was $56,454. The mill will be started when more ore is broken. The North Dome owes the Temiskaming $88,000, and is to be liquidated.——On November 2 the Coniagas will pay a 6% dividend, amounting to $240,000. The usual 3% bonus was passed. Disbursements to date total 181%, or $7,240,000.——The Crown Reserve paid 2%, or $35,276, on October 16, a total of $5,835,574 to date. ——Three inches of 5000-oz. ore has been opened at 530 ft. in the Beaver Consolidated.

The Kerr Lake company will pay a 5% dividend, equal to $150,000, on December 15. This makes 184% and $5,520,000 to date.——On October 3, the Nipissing company's financial position was as follows: cash in bank, $768,757; ore and bullion in transit, $188,582; and ore and bullion ready to ship.

$494,597; a total of $1,451,936.——A new vein at 110 ft. in the McKinley-Darragh property is yielding rich ore, and a winze shows 4 in. of 8000-oz. material, composed of calcite. So far, the winze has produced $30,000. The mines are returning an average of between 125,000 and 150,000 oz. per month.

At Porcupine, a contract for 30,000 ft. of diamond-drilling was recently let by the Dome Mines Co. Ten machines will be used in this work.——The Vipond mill is treating between 90 and 100 tons of ore per day. A refinery is to be built. Work in the mine is being done on three levels.——The Porcupine Crown winze at 500 ft. is being sunk to 600 feet.

The 800-ft. station in the Hollinger is now being cut. From this station a cross-cut will be driven to No. 1 vein, which is yielding ore at 675 ft. and upper levels. At the Acme the shaft is down 550 ft., and will be sunk to 800 ft. to connect with the new level of the Hollinger at that depth. A main central shaft, to serve the Acme, Hollinger, and Miller-Middleton mines, is being sunk 800 ft. south of the mill. It is down 70 ft., and from the 425-ft. level a rise will be driven to meet the shaft. This will be 8 by 32 ft., with six compartments, and two stations, one at 425 ft. and the other at 800 ft. An electric haulage system will be installed for the mines.

At the Kirkland Lake, air-compressors and machine-drills have been started at the Lake Shore and Kirkland Lake properties.

During August the Hollinger mine made a profit of $152,821 from the treatment of 19,828 tons of ore averaging $12.41 per ton. The approximate extraction was 93.01%, and the working cost $3.86 per ton milled, a reduction of 30c. compared with the preceding period. The surplus on hand is $1,043,957.

JAPAN

(Special Correspondence.)—The Hasami mine in Kyshu has been closed on the advice of Reiji Kanda. The Nippon Industry Bank, which had advanced money to the Hasami Gold mines, was obliged to order a cessation of work. In all, nearly $2,000,000 has been spent. A 100-stamp mill was built three years ago, and modern methods and machinery introduced in every department, but to no purpose. Below the main adit level the ore changed abruptly in grade, and in 1913 averaged but 34c. per ton. The occurrence is similar to that at Cripple Creek in Colorado, except that liparite, rather than andesite, is the country rock.

Tokyo, September 11.

MEXICO

According to *The Mexican Herald* of October 17, mining men in Mexico City state that there is a scarcity of cyanide in the republic, perhaps enough to last till the end of the year. Supplies are expected from the United States, while some companies will import from Scotland if possible.

Exchange on the above date was from 21 to 21.5c. U. S. per *peso*.

The International Mining Association of Mexico was formed in Mexico City on October 16. Its object is to aid the mining industry in every way. The following board of directors was elected: T. P. Honey, president; D. F. Calland, vice-president; Emil Berthier, secretary; Andres Aldasoro, treasurer; and A. F. Main, Frank Rule, A. P. Griffiths, Hugh Rose, and Ernesto Enriquez, directors. Among the companies represented at the meeting were: Pachuca and Real del Monte, El Oro Mining and Railway, Dos Estrellas, Mexico Mines of El Oro, La Blanca y Anexas, Maravillas y San Francisco, Sta. Gertrudis, Sta. Ana y Anexas, San Rafael, La Union, Chontalpan, El Barreno, La Esperanza, Guanajuato Consolidated, Peñoles, Santa Rosa Mining Co., El Alacran, Natividad, Bialsdell Coscotitlan, Beneficiadora de Pachuca, Peregrina, Pingüico, Guanajuato Development, Guanajuato Reduction Mines Co., Ajuchitan, El Bote, Carmen Gold Mines, Beneficiadora de Metales, and Metalurgica y Beneficiadora de Zacatecas.

PERSONAL

Spencer Browne is at Toronto.

B. B. Lawrence has been at El Paso.

Howard W. DuBois is on his way to Alaska.

Lawrence Addicks has returned to New York.

Karl Eilers will be in the West for the next few weeks.

Theodore J. Hoover has sailed from New York for London.

J. Kojima is visiting metallurgical plants in the vicinity of New York.

William S. Mann is building a cyanide mill at La Trinidad mine, Cisco, California.

Ross B. Hoffmann arrived in New York on October 18, and will remain there for a time.

Cornelius B. Lakenan, general manager for the Nevada Consolidated, was recently in Boston.

Dr. James Douglas is expected to return to New York from Douglas, Arizona, about November 1.

Morton Webber has left for the West. He recently examined the McIntyre mine at Porcupine, Ontario, on behalf of the Nipissing Mines Company.

Ernest Bamberger, E. L. Carpenter, J. M. Bidwell, and W. H. Eardley are members of a committee for the permanent exhibit of the mining and metallurgical industries of Utah to be at Salt Lake City.

Operating officials at the Santa Gertrudis mine and mill, Pachuca, Mexico, during the past year were as follows: Hugh Rose, general manager; C. A. Lantz, assistant general manager; W. E. Crawford, metallurgist; F. H. Walsh, electrical engineer; and G. F. Johnston, office.

David T. Day has resigned from the U. S. Geological Survey to engage in private practice. Mr. Day has had charge of the work of gathering statistics for the government report on the production of petroleum for seven years, and this work will now be compiled by John D. Northrop.

Operating officials of the Camp Bird company, Ouray, Colorado, are as follows: William J. Cox, general manager; J. B. Glasser, assistant manager; Joseph H. Scott, mine superintendent; and Thomas H. Woods, metallurgist. The personnel has not been changed for twelve years, according to the recently published report of the Company.

Mining engineers on the American committee in London, the work of which is mentioned in an editorial paragraph of this issue, are as follows: executive committee, Herbert Hoover, J. P. Hutchins, A. F. Kuehn, A. F. Martin, and Edgar Rickard; members, A. Chester Beatty, Hart O. Berg, R. Gilman Brown, J. F. B. Erdletts, Jr., C. S. Herzig, Theodore J. Hoover, J. D. Hoffmann, T. J. Jones, Newton B. Knox, A. F. Kuehn, W. C. Madge, J. H. Means, D. P. Mitchell, Walter G. Perkins, C. W. Purington, Jerome Sharp, E. C. Thurston, H. A. Titcomb, C. E. Vigeon, and H. H. Webb.

The nominating committee of the American Institute of Mining Engineers has made the following nominations for officers of the Institute to be voted for at the annual meeting in 1915: For president, William L. Saunders, district 0. For vice-presidents, Sidney J. Jennings, district 0; and Philip N. Moore, district 3. For directors, Samuel A. Taylor, district 2; Robert W. Hunt, district 3; Hennen Jennings, district 9; George C. Stone, district 0; and W. H. Aldridge, district 6. William J. Cox is chairman of the committee.

Andrew A. Bruch, manager of sales for the S. Flory Manufacturing Co., died on October 20. Mr. Bruch had been with the Company since its inception.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, October 29.

Antimony	12 —12¾
Electrolytic copper	13 —13¼
Pig lead	3.75— 4.70
Quicksilver (flask)	$50
Tin	36 —37½
Spelter	6 — 6¼
Zinc dust, 100-kg. zinc-lined cases	10

EASTERN METAL MARKET.

(By wire from New York.)

NEW YORK, October 29.—Lead is firmer at 3.50c., and spelter quiet at 4.90c. per pound. The export demand for spelter has improved. Electrolytic copper is dull at 11.25 to 11.30c. for cash and 11.35c. for 30 days.

A discussion of the metal and cyanide situation appears in the New York letter of this issue.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

The following quotations were made during the past week: New York, 49⅝, 49⅛, 48⅞, 48¾, and 48½c.; and London, 22¾, 22½, 22½, 22½, and 22⅜d. per ounce. During the past 81 years, silver prices, as published in the 'Press' of March 7, 1914, were only as low as the present level during the period of November 1902 to April 1903, February being 21⅞d. in London. The present situation indicates a weak market. The steamer 'Mongolia' took silver worth $224,908 (say 450,000 oz.) from San Francisco to Hongkong and Shanghai on October 24.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Oct.	22 3.50	Sept.	9 3.85
"	23 3.50	"	16 3.85
"	24 3.50	"	23 3.85
"	25 Sunday	"	30 3.75
"	26 3.50	Oct.	14 3.75
"	27 3.50	"	21 3.50
"	28 3.50	"	28 3.50

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	4.28	4.11	July	4.35	3.80
Feb.	4.33	4.02	Aug.	4.60	3.86
Mch.	4.32	3.94	Sept.	4.70	3.82

Apr.	15.22	14.19	Oct.	16.31	....
May	15.42	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

Sales reported in New York during the month were as follows: October 7 and 10, 11.5c.; and 17, 21, 24, and 28, 11.25c. per pound. Exports are increasing, but ships carrying the metal run the risk of being captured and cargoes delayed. For the nine months ended September 30, exports from the United States totaled 569,632,000 lb., against 656,678,400 lb. during the same period of 1913.

The 'Boston News Bureau' makes the following estimate of the copper surplus:

	Pounds.
Surplus, July 1	106,000,000
Production, July, August, and September	400,000,000
Total	506,000,000
Domestic deliveries	130,000,000
Exports	156,000,000
Total	286,000,000
Surplus, October 1	220,000,000

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Oct.	1 55.00	Oct.	15 55.00

May	5.23	4.91	Nov.	5.09	....
June	5.00	4.84	Dec.	5.07	....

The metal is 4.90c. per pound nominal in St. Louis. At Joplin, zinc ore buyers have been bidding better for ore, and prices rose to $41 per ton basis 60% zinc.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	50.45	37.85	July	40.70	31.60
Feb.	49.07	39.76	Aug.	41.75	30.20
Mch.	46.95	38.10	Sept.	42.45	33.10
Apr.	49.00	36.10	Oct.	40.61	....
May	49.10	33.29	Nov.	39.77	....
June	45.10	30.72	Dec.	37.57	....

Tin has risen to 31.75c. per pound. The steamer 'Troilus,' carrying 975 tons of metal from Singapore to London, was sunk by the German cruiser 'Emden,' while the 'St. Egbert' was captured with other lots on board. This has further reduced the visible supply, war risks on shipments have been raised, and buyers are shy of dealing in 'shipment' tin. The oil tanker 'Tamaha' brought 300 tons of tin to San Francisco from Singapore for the Standard Oil Co. on October 24.

The following are recent quotations for large lots in New York: ferro-manganese, $65 to $68 per ton; pig iron, $13.25 to $14.70 per ton; aluminum, 18 to 18.5c. per pound; antimony, 13 to 15.5c. per pound; refined platinum, $48 to $50 per ounce, and quicksilver, $47.50 per flask.

MINERAL STATISTICS

The following data, covering the year 1913, is from the U. S. Geological Survey:

Mineral Output of New Hampshire

Total mineral output was valued at $2,218,925, of which quarries contributed $1,482,771.

Steel Ingots and Castings

The total production of all kinds of this material was 31,300,874 long tons, against 21,599,931 tons in 912. Steel produced by electric furnaces amounted to 30,180 tons, compared with 18,309 tons in the previous year, and 55 tons in 1908. There were 19 complete electric furnaces at the end of last year.

Mineral Output of Connecticut

The total mineral output was valued at $3,795,297, a record total. The products are mainly from quarries.

Mineral Output of North Carolina

Production totaled $3,739,696, an increase of $370,773 over 1912. This is the leading producer of mica in the United States, the yield being $267,913. Other producta are mostly from quarries, there being a little gold, silver, lead, zinc, and copper recovered.

Mineral Output of Vermont

Production totaled $9,647,985, of which over $9,000,000 was from quarries. The yield showed an increase of more than $1,500,000 over that of 1912.

Coal and Gas in Kansas

Out of the total mineral producta worth $27,312,563, coal contributed $12,036,292 from 7,202,210 short tons, and natural gas valued at $3,288,394. These yields were an increase and decrease respectively. Portland cement manufactured was 3,291,818 bbl., worth $3,286,861, a decrease in output but an increase in value. Oil amounted to 2,375,029 bbl. worth $2,248,283, against 1,592,796 bbl. and $1,095,698. The zinc produced was 10,088 tons valued at $1,129,856.

Pig Iron Marketed

The iron marketed waa 30,388,935 long tons, valued at the furnaces at $458,342,345, compared with 30,180,969 tons and $420,563,388, in 1912. The average price per ton in 1913 was $15.08, and in 1912 it was $13.93.

Ferro-Alloys Marketed

Ferro-alloys totaled 296,207 long tons, valued at $13,015,362, compared with 328,685 tons and $12,223,776, in 1912. Of the production in 1913, 121,517 tons was made from imported ores received from Australia, Brazil, Canada, India, Indo-China, and Russia.

Mineral Output of Oregon

This was as follows: total value, $3,563,919, an increase of $1,010,370; gold, $1,627,710, an increase of over 100%; clay products, $771,795; sand and gravel, 1,442,152 tons; stone, $357,498; coal, 46,064 tons worth $116,724; and several other minerals. The last four minerals showed increases.

Mineral Output of New Jersey

Clay products accounted for $19,705,378 out of the total of $37,271,129. Of the clay materials, brick was worth $10,866,833, and pottery $8,838,545. Zinc produced increased from 69,755 to 84,122 tons, but the value declined from $9,626,191 to $9,421,664. The cement output was 4,255,015 bbl., worth $3,638,755, a decrease of quantity but increase in value. Quarries in this state produced a large tonnage.

Metals in Montana

This is essentially a metal-producing state, the value of its copper, gold, silver, zinc, and lead representing over 89% of the total of $69,307,056 in 1913, a decline from the $71,620,873 in 1912. Copper produced was 287,828,699 lb., valued at $44,613,448, compared with 309,738,873 lb. and $51,106,914 in 1912. Zinc recovered in concentrate was 44,337 tons, worth $4,965,693, against 13,459 tons and $1,857,403 in the previous year. This increase was due to the Butte & Superior mine. Coal mined increased from 3,048,495 short tons, valued at $5,558,195, to 3,240,973 tons and $5,653,539.

Metal Yield of Utah

This state ranks second in silver, third in lead, fourth in copper, sixth in gold, and seventh in zinc. The yields were as follows:

Metal.	1912.	Value.	1913.	Value.
Copper, pounds..	137,307,435	$22,655,735	161,445,962	$25,024,124
Silver, ounces...	13,835,903	8,509,080	13,084,835	7,903,240
Lead, tons.....	70,156	6,314,001	83,063	7,309,579
Gold, ounces....	206,360	4,265,851	172,468	3,565,229
Coal, tons.....	3,016,149	5,046,451	3,254,828	5,384,127
Cement, barrels.	760,668	937,119	950,469	1,233,421
Clay products...	.....	724,978	.....	708,906
Total output	.....	$51,004,942	.....	$53,606,520

Iron Ore, Cement, and Copper in Michigan

The total value of minerals produced in this state was $72,143,211, against $80,062,486, due to a strike in the 'copper country.' Iron ore mined totaled 12,668,560 tons worth $33,479,954, a slight decrease in tonnage, but a decided gain in value. Cement manufactured was 4,081,281 bbl. valued at $4,228,879, against 3,651,094 bbl. and $3,145,001 in 1912. The yield of copper, 135,853,409 lb., worth $21,057,278, was only 60% of that in 1912. Michigan is a great salt producer, vying with New York for first place in the Union, and the output in 1913 was 10,829,307 bbl., valued at $3,054,532, a fair increase. A variety of other minerals are produced.

Mineral Production of Colorado

On account chiefly of the decreased production of coal, the total value of the mineral products of Colorado decreased from $58,167,399 in 1912 to $54,294,281 in 1913. The product of chief value is gold, the production of which in 1913 was almost exactly one-third the total value of the mineral products of the state, according to the U. S. Geological Survey. The production decreased from 899,222 fine oz., valued at $18,588,562 in 1912, to 877,857 fine oz., valued at $18,146,916. Second in importance is coal, but on account of labor troubles in the last quarter of the year, production decreased from 10,977,824 short tons, valued at $16,345,336, in 1912, to 9,232,510 tons, worth $14,035,090. The production of zinc, which showed a marked increase in 1912 over 1911, suffered a decrease in 1913, which was particularly emphasized in the diminished value of the output. The recoverable zinc content of the ores mined was 59,673 short tons, valued at $6,683,400, against 66,111 tons, valued at $9,123,374 in 1912. The zinc-mining operations are third in importance among Colorado's mining industries. Colorado leads all of the Western states in the manufacture of pig iron, but produces only a small quantity of iron ore. Silver ranks fourth in Colorado's minerals, and, unlike gold, showed an increase of output in 1913. Production increased from 8,212,070 fine oz. valued at $5,050,423, in 1912, to 9,325,255 oz., valued at $5,632,454. The recoverable lead content of the ore in 1913 was 13,949 short tons, valued at $3,867,502. The other mineral products which had a total value in excess of $1,000,000 in 1913 were clay products and copper. Other mineral products of the state are cement, ferro-alloys, fluorspar, fuller's earth, gems, graphite, gypsum, lime, manganiferous ore, mica, mineral waters, natural gas, petroleum, sand and gravel, sand lime brick, sulphuric acid from zinc smelting, tungsten concentrate, and uranium and vanadium ores.

COMPANY REPORTS

TONOPAH MERGER MINING COMPANY

The report of the general manager, John G. Kirchen, covers the financial year ended April 30, 1913. The main shaft is now 1185 ft. deep, and 7106 ft. of general development has been accomplished in the mine. The Merger vein was cut in the shaft at 940 ft., where it was 14 ft. wide of $25 ore. On and above the 980-ft. level the shoot is 10 ft. wide, and extends 100 ft. above it, the length being 200 ft. At 1070 ft. No. 1 shoot is 180 ft. long, and 10 ft. wide; while No. 2, beyond a fault, is 300 ft. long, up to 50 ft. wide, assaying $10 per ton. Prospecting was done on this level in trachyte formation. At 1170 ft. the west drift showed 400 ft. of ore, which averages $20 per ton over 10 ft. Another shoot was cut in April, with a West End rhyolite foot-wall, and trachyte hanging wall. Up to May 1, it had been opened for 40 ft., exposing 6 ft. of $20 ore. A winze was started from this level, but water hindered work, but in the second week of September 1914 the flow was under control. Ore shipments totaled 14,728 dry tons, assaying 22.5 oz. silver and 0.27 oz. gold per ton, containing 332,057 oz. silver, and 3945 oz. gold. Ore sales amounted to $220,745, from which is deducted mining, $91,249; sampling, freight, and treatment, $93,374; general, etc., $18,555, leaving a profit of $17,668. Added to the previous balance there is a surplus of $170,704 at April 30, 1914.

TOMBOY GOLD MINES COMPANY, LTD.

In his report for the year ended June 30, 1914, the general manager, D. A. Herron, makes the following statement: At the Argentine claims, development was limited to the south end of the mine near manway 119 on the 2100-ft. level. At 60 ft. above the level a drift opened 3 ft. of ore containing considerable lead and zinc, but only $3 to $4 per ton in gold and silver. The winze from this level, started in 1911, is down to 2200 ft., and the vein is being opened. So far it is about the same value as at 2100 ft. Owing to a cave-in in the upper portion of the mine, it was necessary to draw all ore above the 500-ft. level in one area, while the remainder of the stopes above 500 ft. will be drawn during the current year. Pillars of ore supporting the level will be mined and dropped to 650-ft. level stopes. Reserves in the Argentine mine amount to 215,000 tons, of which 190,000 tons is broken in stopes. In the Montana mine, reserves are estimated at 237,000 tons, 137,000 tons being in stopes. Development in this area during the year was 4816 ft. Work at 1450 ft. and the Fortuna level has shown a shoot totaling 2500 ft. in length. Ventilation of the mine has been improved greatly. The aerial tramway worked successfully, only being interrupted by a snowslide which wrecked the Midway tension station and two towers below it. The profit was $40,000, and adding that of the last five months of the previous financial year, the total was $59,000, or $8000 over the cost of erection.

TOMBOY MINE, TELLURIDE, COLORADO.

Ore sent to the mill consisted of 80% Montana and 20% Argentine product, against 41 and 59% respectively last year. There was a decrease in concentrate output, as the Montana ore contains less sulphides. This eliminated recovery of zinc middling as a concentrate product, and consequently experiments with flotation and electrostatic processes were abandoned. As the result of tests by the consulting metallurgist, W. K. Betty, Tomboy ores were proved to be amenable to cyanidation. A 400-ton plant was planned, and in the middle of August 1914, erection of the building was well under way. The mill treated 137,456 tons of ore yielding bullion worth $385,612, and concentrate valued at $573,447.

With dividends from the Tomboy Tramway & Tunnel Co., boarding house, rents, etc., the total revenue was $1,013,918. Mining, treatment, freight, and general expenses totaled $604,377, or $4.40 per ton. Dividends absorbed $297,600, and a balance of $230,000 was carried forward. The consulting engineer, P. L. Foster, rendered valuable assistance in all departments of the Company's operations.

LAKE VIEW & OROYA EXPLORATION, LTD.

This is an English concern holding debentures and preference shares in 8, and ordinary shares in 13 companies operating oil, power, copper, zinc, gold, and dredging properties throughout the world. The report is for the year ended June 30, 1914. The profit was £76,225, and the previous balance of £22,351 made a total of £98,576. Of this, £36,095 was paid as two 5% dividends, the issued capital being 721,909 shares of 10 shillings each. Of the balance, £40,000 was transferred to the reserve account, and £22,481 carried forward. For the current year the first distribution of 5%, or £18,048, has been paid.

The technical committee, consisting of J. A. Agnew, Theodore J. Hoover, J. H. Cordner-James, and A. F. Kuehn, made the following report on some of the interests held by the Company, dated September 25, 1914:

Lake View & Star, Ltd.—The holding Company owns about 62.5% of the capital of this Company, which operates at Kalgoorlie, Western Australia. During the six months ended August 31, its mine yielded 110,917 tons of ore for gold worth £127,735, with a profit of £21,585 above Australian expenses. Dividends totaling 16% were paid in the past financial year, and 5% so far for the current year. Development at 2100 ft. in the Lake View is encouraging, while at and below 700 ft. to 900 ft. the Hannans Star mine is showing good ore. Reserves in the mines total 35,000 tons.

Queen of the Hills Mine.—This is at Meekatharra, Western Australia. During the year ended June 30, 1914, the Holman pneumatic stamps and cyanide plant treated 43,309 tons of ore for £70,200, with a profit of £24,538. The main shaft is down 455 ft. At No. 4 level there is 202 ft. of sulphide ore, 4 ft. wide and worth $7.80 per ton. Cross-cuts indicate a further 3 to 5 ft. of ore. No. 5 level is proving satisfactory also. Ore reserves are 51,246 tons of oxidized and 29,000 tons of sulphide ore. Tests with 731 tons show that the latter ore can be easily treated.

Yuanmi Gold Mines, Ltd.—The Lake View & Oroya company holds 169,036 out of the 350,000 shares of this Company,

operating near Black Range, Western Australia. A miners' strike from June to August interfered with mining and milling. Work in the Oroya Black Range mine failed to disclose any additional ore. Several tributes have been let. The Yuanmi mine made £8100 profit for the five months ended May 31. The shaft is down 519 ft. Reserves are about 40,000 tons averaging $9.12 per ton. The financial condition of the Company is quite satisfactory.

Zinc Corporation, Ltd.—Owing to the war in Europe this Company's South Blocks mill and the flotation plant are closed, although measures are being taken to overcome this situation. During 1913 there was mined and milled 162,956 tons of lead ore, with a recovery of 87.6% of the lead and 70.3% of the silver. The flotation plant handled 350,120 tons of all products, for a recovery of 80.7% zinc, 43.4% silver in zinc concentrate, and 21.8% lead and 37.5% silver in lead concentrate. Ore reserves amount to 971,784 tons averaging 14.8% lead, 2.4 oz. silver, and 9.5% zinc. Development since this estimate, to 1310 ft., indicates another 1,000,000 tons of probable ore. Zinc-tailing dumps at the end of 1913 contained 1,664,000 tons. The profit in 1913 was £225,680. The ore milling plant is being enlarged to treat 300,000 tons per annum.

Burma Corporation, Ltd.—Out of 1,000,000 shares authorized, the Lake View & Oroya holds 100,000 shares. The Burma company is mainly occupied in developing the Bawdwin mines and lead smelter in Burma, India. Development has proved the Burman and Shan lodes to extend to 430 ft. The Chinaman orebody at 1700 ft. is 1300 ft. long. Reserves are 612,000 tons worth £6,920,000 for each 100,000 ft. of vertical extension in depth. The smelter produces about 650 tons of silver-lead bullion and soft lead per month.

Central American Mines, Ltd.—The capital of this Company is 600,000 shares of five shillings each, of which 450,014 have been issued, and the Lake View & Oroya holds 159,824, also £35,000 of debentures. The labor situation at the mines has improved, partly by introducing Spanish miners, and more particularly owing to a more settled state of the country. Water has interfered with underground work. Ore reserves are 61,250 tons worth $9.60 per ton. The mill treated 3602 tons in August. The cyanide plant is being reorganized.

Babilonia Gold Mines, Ltd.—Of the 170,007 £1 shares issued, the holding Company owns 150,007 shares. New pumps have been installed in the mine. Underground work shows about 31,000 tons of $10.16 ore. There is also 25,000 tons of accumulated sand and slime, assaying $6 per ton. The old mill treated 4395 tons of ore for £7578 during the first half of 1914. The new slime plant is in operation. With the exception of the gas engines and electric generator for the new mill, other equipment, including the new Holman No. 3 pneumatic stamp and rock-crusher, have been delivered at the property.

Granville Mining Company, Ltd.—This Company derives its income from the Canadian Klondyke Mining Co., Ltd., and the Canadian Klondyke Power Co. During the 1913 season the four dredges handled 6,363,000 cu. yd. of gravel, yielding 85,899 oz. gold worth $1,331,000, with a profit of $851,000. Results for the 1914 season to September 12 show 49,820 oz. recovered, against 48,499 for the same period of last year. Income of the Granville company from these two companies is more than enough to pay interest on its debentures.

General Petroleum Company.—This Company owns large areas of proved oil lands in California, together with pipelines, refineries, etc. During the quarter ended July 31, 1914, there was 1,319,301 bbl. of oil produced, 725,530 bbl. purchased, 1,396,834 bbl. sold, and 524,587 bbl. added to storage. The total storage at July 31 was 1,501,869 bbl. The interest on notes and debenture stock is in arrear, but on this scale of operations it appears to be amply covered.

The diamond industry of British Guiana has been crippled by the lack of a market. The gold output to September 10 was $682,378, against $943,989 in that period of 1913.

RECENT PUBLICATIONS

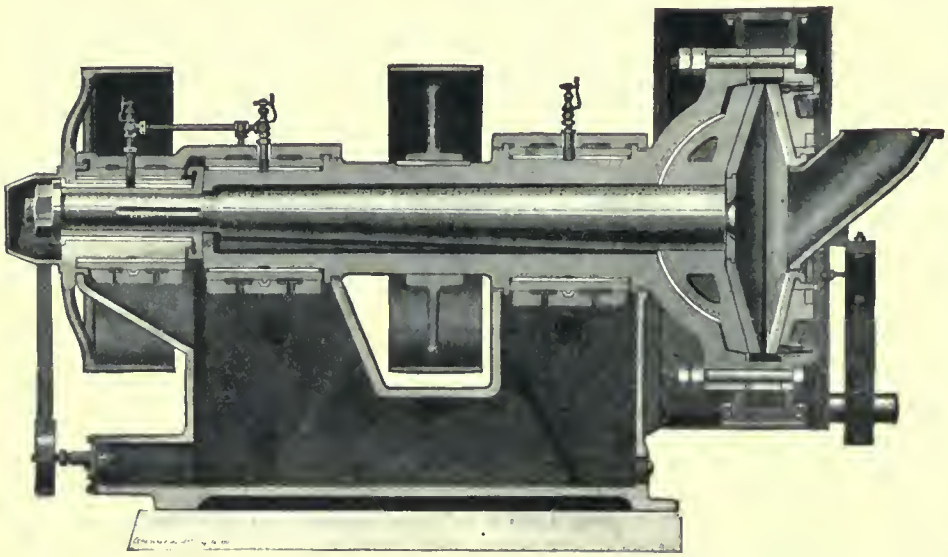
New Machines and Devices

Disc Crushers

Disc crushing is an old principle the application of which to large scale milling operations has been accepted but slowly by metallurgical engineers. The past decade, however, has developed new ideas and refinements in the application of this principle, with the result that disc machines are finding a place in modern metallurgical plants and have given efficient service after passing the experimental stage.

The accompanying halftone presents a cross-section of one type of disc crusher manufactured by the Symons Brothers Co., of Chicago. This crusher is being used in a number of crushing plants and is reported to be giving satisfactory service. The machine is ruggedly constructed with manganese wearing parts. There is no grinding action, the action of the machine being a simple crushing movement. A general idea as to the service of the machine is supplied in a letter from a Canadian operator, who has had a disc machine in service for the past two years.



CROSS-SECTION OF SYMONS DISC CRUSHER.

"The crusher in this instance is a 48-in. disc machine crushing ore composed of greenstone, epidote, magnetite, and a little granite. The granite was much the easiest to crush of any of the four. The greenstone is hard and tough, and has a compressive strength varying from 30,000 to 50,000 lb. per square inch. The material is abrasive because of the large percentage of silica in both the rock and the magnetite.

"The crusher has been used at different times with different sizes of feed. One size being a product from a No. 8 gyratory crusher giving slabs of about 4 in. thickness and a breadth and length much greater. The machine easily handles pieces as large as this, and it would seem will handle pieces up to 6 in. in thickness with equal results. The size of the feed to the machine is only limited by the size of the spout which admits it. The product from the machine will all pass through a 1½-in. revolving screen.

"The capacity of the machine is 50 gross tons per hour, with the machine set to give a product as stated. This machine is driven by a 75-hp. motor and probably uses an average of 60 hp. The inertia in starting is great and it requires a motor of heavy starting torque, and a coil-wound rotor motor is used for this purpose.

"I have no way of knowing, in the absence of data, whether this particular type of machine will make a more dusty product than a gyratory, but observations lead me to believe that there is little difference, if any.

"In studying the machine, one will come to the conclusion that, in view of the fact that there is no differential rotation between the two discs, but simply a nip and, of course, a quick discharge because of centrifugal force, that the machine sizes its product with the largest opening of the discs and not the closest. There is a great amount of tramp steel from the mine going into this crusher and it brings it to an almost instantaneous stop, throwing off the belts and choking down the machine. This, of course, is severe on any machine, but I am unable to remove the tramp steel in the ore with a magnetic separator, since the ore itself is magnetic. This steel getting into the crusher has caused little damage, as during the entire time of operation, nearly two years, only one part, the outer spider, has broken. The machine is rugged and stands a great deal of abuse without apparent injury."

Commercial Paragraphs

MORSE BROS., Denver, Colorado, have issued a folder in which there is listed its large stock of second-hand machinery. Specifications giving details as to size and conditions will be sent on request. The list includes boilers, feed-water heaters, steam and gas engines, direct connected units, motors, generators, water wheels, pumps, compressors, blowing engines, drills, hoists, furnaces, stamps, and other equipment.

GENERAL FILTRATION CO., Pittsburgh, has recently published an attractive booklet entitled 'Filtros.' The booklet discusses the manufacture of this new porous mineral ware, its application to physical separations, filtration, and agitation. The booklet is fully illustrated and contains a large amount of information regarding this interesting product.

ELSPASS ENGINEERING & MACHINERY CO., Denver, Colorado, has for distribution a catalogue, 'The Modern Machine for Uniform Ore Grinding.' The mill discussed is of the well known Chilean type, but involving a decided change in construction and operation. It consists essentially of a heavy, rigid, revolving bed, the bottom of which carries a heavy steel die ring, and upon this ring rest three massive stationary rolls. Instead of these heavy rolls being dragged around upon the die ring by a central moving journal as in the old style of mills, the bed below carrying the die ring is made to revolve beneath the rollers, which remain in a stationary position and merely revolve upon their respective journals as the die ring passes beneath. A number of advantages are claimed by the manufacturers of this mill over the old mill, and details of construction are shown in halftones and line drawings.

HELP THE BELGIANS

The appeal for help for the starving non-combatants in Belgium is one deserving of prompt response. There will be suffering and distress in all the countries at war, and even in such neutral states as Holland, which find themselves surrounded by warring neighbors, but for the present the acute want is in Belgium. However we may divide as to the issues of the war itself, and wherever our sympathies may lie as between the contending countries, we can find common ground in relieving the sufferings of the people of Belgium, driven from their homes, their crops ruined, their food supplies commandeered, and themselves forbidden to take any active part in the warfare. The fight was not of their seeking, though fate placed them at the inevitable centre of the conflict. The disaster that has overtaken this people is beyond comparison with any of the so-called great disasters in our own country such as have frequently called out the generous response that has come to be regarded as characteristic of America. In this instance our own country must take the lead in whatever relief work is accomplished. The other nations are fully occupied, and, too, it is food that is needed, while the Americas form the only available source of supply.

The Belgians are a fine people. Sober, industrious, frugal, they have formed a group in the modern world more important than mere numbers could claim. The Belgian mining and metallurgical industries have contributed much to the world's advancement. The 'Belgian retort' is the basis of zinc smelting, and with but one exception every American zinc smelter uses retorts of Belgian type. So recently as when the United States Bureau of Mines was organized, Watteyne, the head of the Belgian mine inspection service, was called to this country, along with representatives of Germany and England, to advise with Washington officials as to the scope and methods of work to be adopted. There are many ties between the metallurgists and miners of this country and ours, and we owe it to ourselves to help them in this their time of need. That the relief work is under direction of an American mining engineer is a special reason why mining men should take part. That superbly useful citizen, Mr. H. C. Hoover, has asked his fellow citizens here at home to help him in this work, and the response should be quick and generous. We printed last week the names of the mining men serving on the American relief committee in London, and we are glad to note that in the work for Belgium the mining men are equally prominent. Aside from the men in London assisting Mr. Hoover, Mr. Millard K. Shaler is acting as field agent in Holland and Belgium. Having lived in Brussels for the past few years as representative of the Société Internationale Forestière et Minière du Congo, he knows the country and the people thoroughly. On the committee at San Francisco, Mr. M. L. Requa is an active member, and we have no doubt that other mining men will find place in the work as it expands. Support them vigorously.

What is needed now is food: bacon, beans, wheat, canned goods; anything that is staple and can be shipped. A loaded steamer has already been sent from New York by the Rockefeller Foundation, and others will follow. It is proposed to send one or more from San Francisco, and for this purpose supplies will be received and shipped free if delivered to the railroads addressed 'Belgian Relief, San Francisco Chamber of Commerce, Port Costa, California.' Money and checks may be sent to the 'Belgian Relief Fund, Chamber of Commerce, San Francisco, California.' If there is any confusion as to shipments, write or wire to the last given address. While it is food and supplies that are mainly needed, anyone finding it more convenient to do so may send money, which the committee will expend in purchase of supplies. The cost of the transportation has been assumed, we understand, by the London committee. A little economy in your home kitchen or mine boarding house may well permit you to save a Belgian family from starving.

THE medal of the Mining and Metallurgical Society of America is to be awarded this year for 'The Advancement of the Art of Ore Dressing.' Members are invited to submit to the secretary nominations for the honor.

CODE addresses registered prior to July 1, 1914, may now be used in cablegrams sent to Great Britain, France, Russia, Belgium, Japan, and their possessions. Cablegrams sent to Great Britain may be put in code, provided the A. B. C. (fifth edition), Scott's (tenth edition), Western Union, or Liebers be used and indicated. Coded messages are, however, subject to delay incident to translation and submission to the Censor. Messages to Germany and Austria may be sent in Eng

lish, German, French, or Spanish, by way of Tuckerton, New Jersey.

IN connection with the tribute to the late Thomas J. Grier appearing upon another page, it is interesting to recall that he never owned a share of stock in the great mining company for which he worked. While Homestake shares are not the basis of speculation, Grier preferred to be free from any possible implication of serving self interest in case they rose or fell.

MEMBERS of the Geological Society of America have recently been notified of the nomination to correspondentship of Messrs. A. Lecroix, professor of mineralogy, Museum of Natural History, Paris, France; Charles Lapworth, professor (emeritus) of geology, University of Birmingham, England; Albrecht Penck, professor of geography, Royal University, Berlin, Germany; J. J. Sederholm, director Geological Survey of Finland, Helsingfors, Finland. The election of these men at this time emphasizes the welcome fact that in science there are no national boundary lines that must be respected, and in honoring such scientists the Society honors itself. The annual meeting of the Society is to be held at Philadelphia, December 29 to 31, inclusive, and Mr. G. F. Becker, the retiring president, will lecture upon 'Isostacy and Radioactivity.' A pleasant feature of the plans for the meeting is the suggestion from the secretary that if fellows of the Society will indicate the names of students who might wish to attend the meeting, invitations will be addressed to them. It is a good thing to see that the beginners have every opportunity.

COMPARISONS between the value of ground as shown by drilling and the recovery made in gold dredging are difficult and usually uncertain. The figures that Mr. Charles Janin presents on another page are much the most accurate that have come to our attention. If one but stand on a dredge while it is at work he will realize quickly the practical impossibility of running an accurate dredge test comparable to a modern mill test. The situation would be similar if the ore went through the mill without crushing. How is an accurate sample to be taken? How can the dredge master really know the value of his feed, and, without it, how is he to know accurately his metallurgical losses? He cannot, and does not. What he does is to watch the tailing, especially the fine material. Incidentally he is fortified in his conclusion that the metallurgical work of the dredge is well done by the fact that adding plates and tables improves recovery little. The great bulk of the gold is saved, as Mr. Janin shows, on the first few feet of tables. Possibly a time will come when closer saving will be attempted on part of the material, but till now the easier path has been to reduce costs by increasing capacity, and results would seem to have justified that course. As to valuing the feed, reliance is still placed upon testing the ground in place. The difficulties and dangers in this process have been indicated in the discussion on 'Valuing Placer Ground' that has been running for some time in the *Press*. We believe one most important factor is the relative uniformity in size of the gold particles, but must reserve discussion till another time.

THE United States Bureau of Mines has begun the collection of a general library of petroleum literature, under the direction of Mr. W. A. Williams, chief petroleum technologist. The details of this work have been assigned to Mr. David T. Day, who has recently been transferred from the United States Geological Survey. The importance of such a library is so manifest that it is hoped all technologists will aid in the work by exchanging with the Bureau all available books and maps on this subject.

RESIGNATION of Mr. George E. Roberts from the directorship of the Bureau of the Mint to assume the presidency of the National City Bank, after serving under an administration in which Mr. W. J. Bryan is Secretary of State, suggests interesting changes in American life. When Mr. Bryan first ran for President, in 1896, Mr. Roberts was editor of a country paper in Iowa. Those who remember the famous 'free silver' campaign waged by Mr. Bryan will recall 'Coin's Financial School,' one of the documents of the crusaders that put half truths in a striking and plausible form that made them especially effective. Mr. Roberts set out to answer that book. Always a student, he went first to the State Library at Des Moines to brush up and renew his earlier studies of financial matters. Having got to the bottom of the matter, he wrote 'Coin at School in Finance,' which proved the most effective of the various replies called out by the troublesome booklet of the free silver advocates. Mr. Roberts' work was recognized, and McKinley offered him the post of Director of the Mint, which he has held since, except for a short period when he occupied an important post with the Commercial National Bank at Chicago. His duties at the Mint have been most congenial, and while he has written little, his studies have been deep and thorough. He has been a frequent visitor to the mining districts of the West and has come to be widely known in person among mining men as well as among financiers. The modest looking Mint reports issued by him are mines of accurate knowledge, and it is not surprising that he has been called to the important post in New York, though there has been no hint of friction at Washington. The various honors that have come to Mr. Roberts are a pleasing indication that in all the hurry of American life, with all its reputed rush for effect and immediate results, the modest honest student does nonetheless get recognition if his work is good and he but keep his feet on the ground as well as his head in the clouds. The National City Bank is a powerful organization. Its move in establishing branches in South America and in beginning publication of *The Americas*, a monthly devoted to upbuilding trade between the United States and Latin America, indicates the broad policy that is being pursued. In this organization Mr. Roberts will find congenial helpers and in his new position a wide field for usefulness.

LABOR AS AN INVESTMENT

In every individual organization, labor is the principal item of production cost, often amounting to 80 per cent of the total. The effect of competition in the industrial world has been to compel close study of production costs and methods, with the result that both equipment and methods are constantly being improved. But labor, as a part of production cost, although the largest item, involves the personal factor, and has been the last to be the object of scientific study. Notable results have already been attained, but largely in roundabout ways. Thus, for example, a manufacturer who is obliged to compensate his workmen for injuries sustained has their eyes examined to find out whether their sight is keen enough to enable them to avoid injury, and incidentally learns that a near-sighted workman gives a poor return for the wages paid him. Furnishing him with glasses costs the company a small sum which is returned in the form of increased output or better work within a short period. On another page Mr. Fred H. Rindge, Jr., secretary of the industrial department of the Young Men's Christian Association, points out some of these aspects of the study of labor problems.

The world grows more intelligent yearly, and has outgrown many narrow-minded views that were formerly held. An employer can now make evident his wish that his employees should keep away from saloons, fix up their houses and gardens, and even go to church on Sunday, without being considered a pious crank or one who would deny amusement to the laboring man. The general public is now intelligent enough to see that a workman who spends his time off shift in getting drunk and picking a fight is a poor workman while he is working and the cause of a lot of trouble when he is not. The right of the employer to control in some degree the private life of his employee will inevitably win recognition in the end. The attempt of labor unions to compel the employer to pay an inefficient employee the same wages as an efficient one cannot possibly be permanently successful, for it is contrary to natural laws, and though such attempts are often for a time successful they necessarily break down in the end. Another narrow-minded view that is also passing is that Christianity essentially consists in the pious observance of certain religious ceremonials, such as the singing of psalms and the reading of the Bible. As a matter of fact, Christianity introduced, into a world governed only by selfish considerations, the vital idea that a proper regard for the welfare of the other man is the first essential in securing our own best interests, and not even the many absurd and contradictory features which zealous but mistaken adherents have foisted on Christianity have been able to obscure this real contribution to human life.

It is in this fundamental sense that the Y. M. C. A. is a Christian Association, and it is because of this, and also because of its emphasis on the care of the human body that the work of the Association has prospered and will continue to prosper. In other industrial fields the Association has been a useful ally of the employer, and we believe that mining companies generally have too much neglected an opportunity for coöperation with the Association which would be greatly to the advantage of the companies.

PRECISION OF THOUGHT

One of our contributors recently protested at what he thought to be an error made in printing his article. He had written, "Of the tonnage hoisted, 626,000 tons *were* crushed," and supposed our use of the singular form of the verb a misprint. We were glad to explain to him that his own error had, in matter of fact, been corrected. As this error, using the plural of the verb following a collective subject, is exceedingly common, it is well to refer to it at some length, since it illustrates a principle and may serve to point a moral.

The verb following a collective noun may be either singular or plural, according to which is meant, and everyone who cultivates precision of thought and of the use of language will be careful to use the singular when the singular conveys the desired meaning and, similarly, the plural when it is required. Thus we may say "the football team has gone to Annapolis"; meaning that the team, considered as a unit, has proceeded to that place. It would be correct to say "the football team are enjoying themselves in Annapolis, following the game," the meaning here being that the individual members of the team are enjoying themselves, each in his own way. Many similar instances will at once occur to the reader. To say that the 600,000 tons were crushed would imply that each ton was separately crushed, like 60,000 walnuts cracked with a hammer. But this was not the process employed; a quantity which is expressed in terms of tons was crushed, and no individual entity is implied. It might be correct to say that five tons were crushed, if there were five one-ton lots of ore, each of which was crushed separately. Such form of expression is undesirable, however, for it was ore that was crushed, not a ton. There may be many who think that the observing of such distinctions is a useless refinement of language, but nothing could be further from the truth. Thought and expression are closely linked, and a man who is habitually careless in his speech and writing will necessarily be careless in his thinking as well. Putting this thought in another way, it may be said that careless speech is the outward expression of loose thinking, and as accuracy of judgment is a prime virtue in an engineer, it is well worth while for him to cultivate precision of speech in order that he may not be suspected of loose thinking, which will inevitably lead to wrong decisions. Nor can the reflex action of speech on thought be neglected. Care and precision of expression, both oral and written, will inevitably be followed by an increase of ability to think clearly and precisely, one of the attributes of an engineer that is most worth while cultivating.

A LESSON IN MINING TO A CLASS OF ALIENS.

Big Returns on an Investment

By FRED H. RINDGE, Jr.

Big returns on an investment? What kind of an investment? An investment in which practical business men are becoming more vitally interested every day. An investment which is increasingly essential to the largest success in any industrial operation. An investment which pays in terms of human kindness and in dollars and cents. An investment in men. Arthur D. Dean, of the University of the State of New York, has expressed this idea in a recent commencement address:

"The scientific world knows that a pound of coal, black and inert mass that it is, has locked within it elements which will give us heat, or power, or light. If we wish to have warmth of body, we burn the fuel in our fireplace. If we wish to feel the throbs of industry, we develop horse-power through the expansive force of steam. If we prefer light for the printed page, we pass electrical energy through the tungsten filament. Excepting the perpetual motion believer, no one dares to say that the 16-candlepower lamp has more energy than the one-tenth of the horse-power of a lathe, or the equivalent number of heat units extracted from the coal. To the mechanical engineer it is all a question of what he or his client desires—whether to keep warm, to manufacture, or to see in the darkened night. To the social engineer, the lump of humanity may be blackened, its possibilities locked up and inert, or it may turn the materially productive wheels of a modern industry with its workers as unsocialized and mechanical as the very wheels themselves; or this lump of humanity, by the inventive genius of the progressive, may

A CLASS BEING INSTRUCTED IN FIRST-AID WORK.

become a source of light—a glowing mass of an enlightened humanity."

In these days, who is the progressive? Surely he is the engineer, the manager, the employer of labor who is interested not only in his machinery, but also in his men. The industrial leader who understands his men, who is interested in improving the conditions under which they work, live, and recreate, who is fair and just in all treatment of his employees, and whose men manifest that spirit of loyalty so prominent in some companies and so lacking in others—this man will in the long run be the one who can maintain the highest standard of efficiency and who receives the largest returns, both human and material.

Scope of Betterment Work

No student of modern tendencies can doubt that the whole country, in fact the whole world, is being forced

to pay more attention, directly or indirectly, to the 'man on the job.' Big business is spending enormous sums of money in industrial betterment work, and there seems to be not the slightest doubt of big returns on the investment. During 1913 the United States Steel Corporation and its subsidiary companies expended over $7,000,000 in improving the condition of its workmen. Over $3.000,000 of this was for relief of injured men and their families, over $660,000 was spent in accident prevention, and more than $1,600,000 was spent in sanitation and welfare work. From this, the world's greatest corporation, employing about 230,000, down to small concerns employing as few as 30 men, employers are more than ever alert to their human responsibilities. To be sure, an expenditure for welfare work is no proof that evils do not still exist, and it has been said by some critics that welfare work is only a salve to cover certain evils and to heal otherwise open sores. Nevertheless, this expression of interest in men, whether it be from the human or economic motive, is certainly a great step in the right direction.

An Example or Two

I have just read the welfare booklet of a well known company and was impressed by this paragraph:

"This company, like many corporations of the present day, realizes the importance of educational courses in the efficient management of business. Two factors enter largely into the success of a business—the quality of goods sold and the quality of service rendered. The man who stands behind the counter, who receives business over the telephone, who canvasses for customers, is now being taught his work as fully as is the technical apprentice who is learning to produce the goods. Another point of view fully considered in maintaining our educational courses is the immense advantage to the employee himself." Education pays.

Thomas Darlington, secretary of the Iron and Steel Institute, who has accomplished so much in sanitation and health work, has repeatedly proved the relation between health and efficiency. He even goes so far as to say, "The efficiency of employees depends on several factors, of which health is the most important." Wholesome food, pure drinking water, proper housing, right clothing, good ventilation and lighting, sanitary surroundings, accident prevention, etc., may have more influence in determining a man's real value than we generally imagine. Surely the Panama canal could never have been built unless our government officials had given primary attention to the health and recreative conditions surrounding the workers. Physical welfare pays.

And how about leisure conditions? An employer recently said to me: "I don't care what my men do outside the shop. That's not my business. They can go to the devil for all I care!" Needless to say, his business is nothing to boast of. Wide-awake employers do care what men do outside the shop. It makes a lot of difference with Monday's output, whether the men have been spending Sunday in rest and recreation or in drink and dissipation. That is one reason why so many companies provide good homes, playgrounds, libraries, clubhouses, and the right opportunity for wholesome social intercourse. Social welfare pays.

There is a fourth thing, more important than education, physical welfare, or social welfare. Careful students of this whole problem would probably agree that at the base of individual inefficiency lie many causes, but at the root of these causes is one underlying, namely, a lack of that almost indefinable something which we may safely call character. The man who possesses good character is certainly more likely to be efficient than the man who lacks character. His character may in large measure determine his ambition, his desire for education, his outreach after health, his friends and associates; in short, those things which, altogether, make him the kind of man every employer wants and needs in his business. The building of character pays.

When I say that all these things pay, I do not wish to give the impression that industrial betterment exists only because it pays. It is probably fair to say, even though the fact that it pays is a very important and fundamental reason, that most employers are interested or soon become interested in the human side of their business as well. Mining operators are not exceptions in this particular, and I have met scores of mine superintendents, managers, and other company officials who are interested in their men and who are sincerely trying to help them. To be sure, there are also mining men who are selfish and blind to the movement.

Reasons for Failure

Other mine operators are somewhat embittered because they have attempted welfare work and failed in whole or in part. Experienced welfare experts will probably agree, however, that such failures can be traced to very definite causes. Among these might be mentioned paternalism, failing to secure coöperation of the employees, neglecting to give the workers representation and responsibility, initiating the work and expecting it to run itself without competent paid supervision; attempting to maintain the activities without an experienced welfare secretary or his equivalent in charge; promoting one activity, instead of all-round activity which would help the whole man; making the welfare work an advertising feature. Other causes for failure are the ideas prevalent among the employees—whether justified or not—that the company is promoting welfare activities instead of improving wages; attempting to cover real evils by clubhouses; using welfare work to retain good help; to prevent employees feeling a need for a larger share in the control of industry; and the feeling (even without any special reason) that the company is trying 'to put one over.'

Work of the Y. M. C. A.

It is interesting to note that the Young Men's Christian Association, in its industrial betterment program, has generally prevented in its own work these very

causes of failure. Many employers prefer to let the Association promote their welfare work rather than promote it themselves. It then becomes the Association's work, and the Association enters the field as an independent agency working in the zone of mutuality and coöperating with both employer and employee. The company contributes, the men pay membership fees; the employer advises, the employees suggest, and there can be no paternalism. An experienced Association secretary is placed in charge, and he is carefully supervised by state and international committees. Through these supervisory agencies there is a constant inflow of new principles, new ideas, new methods, and the thing naturally succeeds.

All this is fact, not theory. Some may be surprised to learn that the Young Men's Christian Association in North America has in its large membership nearly 100,000 industrial workers, while 400,000 more are reached in extension activities. This does not include 500,000 men served by Railroad Associations. During the past eight years the Association has also been dealing very effectively with the immigrant. Fifteen secretaries are now serving foreigners as they embark at fifteen different ports of Europe;* others teach them English and give stereopticon lectures, etc., in the steerage; a dozen other secretaries with remarkable linguistic ability continue the chain of service at Ellis Island and other ports of entry; others meet immigration trains at points of inland destination. Then the final service begins in the form of finding suitable lodgings, securing employment, teaching English and citizenship, and acquainting the newcomers with American customs, laws, and institutions.

A special method of teaching English to foreigners has been devised by Peter Roberts, one of the secretaries of the Industrial Department of the Y. M. C. A. International Committee. This is being used with special effectiveness because the lessons deal with practical daily experiences. Special mining lessons have been prepared, and one book published by the Scranton Y. M. C. A. and the D. L. & W. R. R. company contains lessons on 'Mine Accidents and their Prevention.' Pictures and dramatic action make these lessons very interesting and easy to learn. The method has been illustrated in 'talking motion pictures' by Thomas A. Edison, Incorporated. During the past year over 310,000 foreign men were helped by the Young Men's Christian Associations.

One very interesting development of the Association's work is what is known as the Industrial Service Movement. Realizing the problems and opportunities already indicated, this movement is helping to develop the right kind of industrial leaders for the future. It is in very close relation to the colleges and engineering schools of the country, and is helping to bring to the fore the human side of the engineer's job. During the past year the movement has enlisted, through the coöperation of student and city branches of the Association, 3500 college men in practical service for industrial workers. These students, coming from 160 colleges, have helped 60,000 working men and boys, and the work has made an impression on the lives of both student and workingmen which neither group will ever forget. The collegians have taught foreigners English and civics, instructed American workingmen in mathematics and other subjects, led clubs of industrial boys, and rendered many other forms of service. In this personal contact, engineering students particularly have come to understand industrial men. They have developed many of the desirable qualities for successful industrial leadership already mentioned, and are graduating from college with a new vision and a new determination to be leaders rather than drivers of men.

ENGLISH LESSON ILLUSTRATED BY MOTION PICTURES.

Many of these leaders have already entered the mining industry. In fact, all of this work which has been mentioned is bound to make an impression on mining and other industries of the country. J. Parke Channing, vice-president of the Miami Copper Co., recently wrote: "It is needless to say how much I am interested in the Industrial Service Movement. The principle is to my mind undoubtedly a sound one, and I can already, in my own experience, begin to see the good effect it has, not only upon the young men who are engaged in this work, but also upon the men to whom they are devoting their energies. You may be sure that I will do everything possible to forward the movement, which will undoubtedly tend to better efficiency in all industrial work."

The Association is operating successfully in connection with eighty special industries—mining, lumber, cotton, quarrying, and others. The Association has for sev-

*This port work has been temporarily interrupted by the war.

eral years been operating in coöperation with many coal, copper, iron, and silver mining companies. J. A. Holmes, director of the U. S. Bureau of Mines, says: "I am interested in the Y. M. C. A. because during the past twenty-five years, as I have passed up and down through the great mining regions of Pennsylvania, I have seen places transformed through its work." The work has been especially promoted among the coal miners of Pennsylvania, West Virginia, and Kentucky; among the copper miners of Michigan and Arizona; and among the iron miners of Tennessee and Michigan.

The Benham Clubhouse

Cyrus H. McCormick, president of the International Harvester Co., speaking at the opening of the Y. M. C. A. building at Benham, Kentucky, said: "In the effort to make Benham an ideal mining town, we are glad to provide this clubhouse. Directors formerly felt that corporation funds could not be applied to the erection of such a building as this, but within the past twenty-five years this has changed; the corporation has developed a conseiousness, and no longer is corporate action permitted to hide behind the anonymous charaeter of its organization. The Y. M. C. A. is an organization for the betterment and uplifting of mankind, for the development of a strong, manly Christian character and for promoting good fellowship. It has long passed the experimental stage. Its influence is world-wide and its work is invaluable in every community." An illustration of the Association's adaptability is furnished at Buxton, Iowa, where the work is for colored miners. The general manager writes: "The Company considers the money well spent. The influenee of the good your organization is doing is felt throughout the entire state. Long may it continue."

One may rightly ask, "What does the Association do in a mining community?" Here is a list of activities actually being carried on:

To Increase Industrial Intelligence.—Reading-room, library, educational leetures, practical talks, educational clubs, mining clubs, bands, debating societies, first-aid corps, garden clubs; elasses in writing, arithmetic, grammar, theory and practiee of mining, meehanical drawing, designing, manual training, domestic economy, hygiene, and other subjects.

To Conserve Health.—Gymnasium elasses, shower and plunge baths, bowling, billiards and pool, barber shop, health talks, physical examinations, medical examinations, athletie contests, baseball, tennis, and other games, camping and swimming, tramps and hikes.

To Cultivate the Moral and Religious Interests.—Religious meetings, illustrated talks, life problems classes, Bible classes, noon-hour meetings, union Sunday-schools, cottage meetings, training classes, men's meetings.

To Aid the Community Life.—Clean-up campaigns, campaigns against tuberculosis, flies, mosquitoes, etc., community meetings, village fairs and picnies, May day, safe and sane Fourth of July, circus (local talent), stereopticon entertainment, Boy Scouts, Lyceum features, savings funds, eivic leagues, health lectures, flower and vegetable planting, reading-rooms, moving pietures, home talent elubs, refreshment counters.

To Provide a Social Centre.—The building is a social headquarters. Social meetings, social games, and social elubs are promoted, and all activities are pervaded by the social spirit.

Every mine-worker holds in his hands the lives of his fellow-miners and the property of his employer. He can cause far-reaching suffering and untold damage to property by a stupid or vicious act. Any agency which can improve the education, physieal welfare, social welfare, and character of men will increase their efficiency. Such an ageney is worthy of serious consideration on the part of the operator. Practieal money-making, industrial leaders (even the unsentimental ones) have found that such a factor in modern industry develops trustworthiness, higher standards of workmanship, and makes possible that kind of intercourse between employers and employees which begets good will; and good will raises all other forces in industry to a higher power. The right kind of an investment in men will yield big returns.

Custom mills are operated in Western Australia by the government, and in 1913, according to the Department of Mines report just to hand, there were 37 stamp-mills, sand, and slime-treatment plants at work. A total of 60,573 tons of ore was crushed yielding gold worth £185,699 by amalgamation. Sand and tailing treatment dealt with 41,378 tons, slime treatment 6089 tons, and 8032 tons of tin ore. The total tonnage of all material was 106,072. The revenue received by the department from all plants was £47,991, and expenditure £55,362, making a loss of £10,531 for the year; but adding profit, etc., at two mills, the net loss was £7712. Since the inception of government owned mills in the state, 960,989 tons of gold ore has been treated for £3,528,996 by amalgamation, £478,383 from sand treatment, £101,942 from slime treatment, and £80,835 from 64,920 tons of tin ore; a total value of £4,189,955. Capital expenditure on all the plants to date amounts to £332,378; total revenue, £937,604; operating loss, £48,112; interest and sinking fund on capital, £149,015; depreciation, £216,838; and a grand loss of £413,965. The benefit of these mills in opening remote districts, and mines which otherwise would never have been developed, has been of the greatest value to the mining industry.

During the four weeks ended September 20, the Mt. Morgan mine in Queensland produced 708 tons of copper and 8580 oz. gold; also 1747 tons of concentrate containing 134 tons copper and 1320 oz. gold. Matte on hand contains 105 tons copper and 1230 oz. gold. Owing to the great amount of gold in its copper ore this mine can continue to operate its smelter and concentrating plant. The approximate value of the copper and gold output during this period is $210,000 and $198,000 respectively.

Recovery of Gold in Dredging

By CHARLES JANIN

The percentage of recovery made by a dredge as regards either the actual gold content of the material dredged or the yield indicated by prospecting, has always been an interesting question. It is generally acknowledged that the modern dredge, with its improved washing plant and large area of gold-saving tables, recovers, except where considerable sticky clay is present, a high proportion of the gold in the material washed. The percentage of gold recovered out of the amount estimated to be in the ground is a different matter, and requires the consideration of several factors not directly connected with the metallurgy of gold dredging. Obviously, to determine the difference between the actual content of the ground and the recovery by the dredge, it is necessary to know:

1. The gold content of the ground previous to dredging, or
2. The loss in the tailing.[1]

Too much dependence placed on a vendor's statement of past production or his estimate for the future often accounts for a wide discrepancy between the expectation and the fulfillment. The same may be said concerning careless or inexperienced sampling, or, in some cases, the entire absence of sampling. In the early days of dredging, inexperience in the use of drills for sampling placers was often the cause for an overestimation of the gold content, this accounting in part for the fact that the first dredges recovered a low proportion of the gold indicated by drill-sampling. Experience has minimized this danger, so that the results obtained over a period of years have shown that there is little reason today for a wide discrepancy between the actual recovery and the content estimated by prospecting, provided the work has been done by an engineer accustomed to this line of work, with sufficient funds and time at his disposal.

The thorough sampling of a placer property is by no means the simple matter the uninitiated often believe it to be. Much depends upon the care taken and the experience of the engineer in charge. A great deal has been written on the investigation of placer areas by a number of engineers familiar with this class of work, and it is not my intention to go deeply into the matter at this time.

If great care has been exercised in taking samples, the work being done properly in every detail, each sample will then represent as nearly as possible the mineral content per cubic yard of the place sampled. While each hole may then be taken as indicative of the content of that portion of the ground where it is sunk, the placing of holes is an important factor. The location and distances apart at which samples should be taken can be determined only after a study of the ground has been made. There is no hard and fast rule to follow. Some areas have been considered sufficiently prospected with one drill-hole to ten acres; on other areas the engineer has not been fully satisfied with one hole to one acre. Preliminary holes are generally sunk and carefully sampled to determine if the gold occurs in wide or in narrow channels, and if it is fairly evenly distributed throughout the deposit, or occurs in irregular pay-streaks. Holes badly spaced with too many sunk in the richer portions would yield too high an average content. As stated above, there is no rule as to the number of holes to be sunk, but on ground that shows spotted or irregular contents, obviously more tests will be necessary than where fairly uniform samples are obtained. Where sampling discloses the existence of a channel or narrow belt having a higher mineral content than is found in the area as a whole, then the outlines of such a channel or belt should be determined as closely as is warranted for the purpose of the examination.

Sometimes it is feasible to segregate certain portions of a property, eliminating low-grade areas. On large tracts, where time for the examination is limited, tests to confirm the samples indicated by preliminary prospecting may be concentrated on a piece of a sufficient size to determine the advisability of purchasing the property and installing at least one dredge. The accuracy of the average mineral content of placer ground indicated by the examination depends, therefore, upon the care taken in sampling, the number of samples taken, and the situation of the holes in relation to the character of the deposit. All hinges upon the experience and judgment of the man in charge.

In estimating the recovery from dredging ground after determining the average content indicated by prospecting, most engineers take a proportion, generally 75 or 80%, of this indicated content as the amount recoverable by the dredge. These figures are based upon actual tests made to determine the dredge recovery, and also upon the percentages of the prospecting content recovered from certain areas that have been dredged after careful prospecting.

Some engineers, when sampling by means of drills, use a different factor in their calculations than that generally used: that is, they reduce the metal content per cubic yard of the place sampled by an amount which, in accord with their experience, represents recovery. The use of this factor, which is practically a combination of drill factor and recovery estimates, discounts the content that otherwise would have been assumed from the regular drill factor. Engineers following such a practice should mention it clearly in their report. Failure to do so might cause the future of a property to be further discounted by those to whom the report is pre-

[1] A few of the figures in this paper were previously used by me in an article published in *The Eng. & Min. Journal*, January 27, 1912.

Percentage of recovery based on weight of amalgam, covering a period of three years.

sented, if not conversant with the computation methods.

The following reference to the Pato property is taken from the report of the Oroville Dredging company, dated September 30, 1911, showing the prevailing practice of discounting prospecting indications. "The original estimates by the engineers give us an area containing 13,637,347 cu. yd. of material, yielding gross $3,202,986, there having been deducted 25% for variations, possible losses, etc."

The Gold-Saving Table

The accompanying sketch of the gold-saving table of a 6-cu. ft. close-connected bucket-dredge, furnished by W. H. James of Oroville, shows the percentage of the total gold recovered from different portions of the table, careful data having been kept at each clean-up for a period of three years.

The total table-area is 1457 sq. ft., 89% of the gold recovered being arrested on 292 sq. ft., as shown on those portions of the table marked I. Including the recovery from the save-all, 92.2% of the gold was obtained from 332 sq. ft., and 4.68% more was recovered from 360 sq. ft. additional. Thus, 96.9% of the total gold recovered on this dredge came from 692 sq. ft. of table-area. The remaining 3.1% was obtained on the additional 765 ft. While the total table-area on this dredge was 1457 sq. ft., that on a dredge having the same bucket capacity but designed for ground containing much clay and difficult to wash was increased to 3800 sq. ft. Table-area varies with the ideas of designers and with the conditions to be encountered. From the first dredges with only a few square feet of table-area to the modern 15-ft. dredge with 8000 sq. ft. is a long step, as is also the capacity of 10 or less cubic yards per hour of actual running time as compared with 500 cu. yd. per hour for months at a time as achieved by some modern boats.

The sketch herewith is interesting as showing how large a proportion of the gold recovered is obtained on the upper part of the table. The bulk of all the gold recovered is actually taken from the first three feet at the top end of the table. It is advisable, however, to have as large a table-area as space on the dredge will permit, even though it is not often necessary to clean up the lower end. Few operators have ever complained of having too great a table-area on their dredge, and many would add to the existing tables if space permitted.

It is difficult to sample the dredge-tailing. Any test, to be trustworthy, must extend over a considerable period. Practically all such tests have indicated an appreciable loss, but the tests, in most cases, did not, so far as I know, determine the gold recovery with any accuracy. Most statements of exact percentages of loss of gold have proved, upon investigation, to be merely guesses made by the dredge-master. In connection with one of the most thorough tests made for this purpose, at Oroville, a small bucket-elevator was used, the material being taken by means of perforations in the bottom of the tailing-sluice. This passed to a small wooden sump in which the lower sprocket-wheel of the elevator was mounted. The material was somewhat concentrated, owing to the method of collection, but this could not be avoided. The speed of the elevator was arranged so that approximately two cubic yards of material would be collected during the shift. This collected tailing afterward was carefully washed through a rocker, and panned. All of these tests showed an appreciable loss of quicksilver and amalgam, but no definite figure of loss that could be compared with the total gold content of the material handled was obtained. In general it may be said that the loss of gold in the tailing is less than the amount lost in front of the boat from bucket-spill that is not caught in the hopper and save-all. It is estimated, by those competent to judge, that the average recovery of the actual gold content, while varying under different conditions of operation and efficiency of labor, is not less than 90% under normal conditions, and in some cases it may be considerably in excess of this figure. Compare this with the following extract from *The Canadian Mining Journal* of January 30, 1903, in reference to the old Cobeldick dredge at Lytton: "The director who was sent out from England to investigate for the company the working of the dredge made the *discovery* that of the gold dredged up from the bottom, less than 10% was recovered on the tables, the remaining 90% going off again with the tailing, although the saving appliances on this machine were about the most complete of any in British Columbia." It would be interesting to learn what tests the director made to arrive at this conclusion; probably the recovery was only 10% of the estimated amount, and the blame was put upon the gold-saving appliances, and not where it rightly belonged.

In a careful test to determine dredge-recovery, 22 holes were sunk on a measured area. Results were from 3 to 52c. per cu. yd. and averaged 19c., the regular drilling factor being used in these calculations without allowing any discount for recovery. In working, the recovery was, as near as I can remember, 17c. per cu. yd., or about 90% of the content shown by averaging the samples obtained in drilling. Those companies in California that get the highest recovery of the estimated content are those that previously have discounted the prospecting indications by 20 or 25%. To have much value the recovery percentages based on prospecting must be founded upon bank-measurement of the yardage handled, not upon the size of the dredge-bucket and the running time of the dredge.

The following results, obtained by a California company operating one dredge only, are of considerable interest, as careful records were kept from the beginning of operations.

Acres dredged	144
Cubic yards	6,980,800
Gold content per cubic yard as shown by drill holes before discounting, cents	21.05
Actual recovery	12.92
Percentage of recovery of amount indicated by drill-holes	61.38
Drill-holes to area: approximately 1 hole to 3 acres	47

Results from a Small Area

Acres dredged	40
Cubic yards dredged	1,232,868
Prospecting content, cents	17.18
Recovery	15.35
Percentage	89.34

Six holes to 40 acres.

The results obtained from the dredges of the Natomas Consolidated and those of the Yuba Consolidated are of special interest on account of the magnitude of their operations. The amount handled by the dredges of the Natomas Consolidated from the commencement of operations to December 31, 1913, have been in excess of 102,000,000 cu. yd. In regard to the recovery, the following excerpt is taken from C. M. Rolker's report on the Natomas Consolidated, made in 1909. "The writer wishes to emphasize that according to the statement of the general manager, Newton Cleveland, the values of the different bore-tests, which are marked on the Company's map, are the original values calculated, reduced by 15% to make them representative of recovery." In 1913, Frank Griffin, the president of the Natomas company, stated that the recovery made by the dredges was 15% less than the engineers estimated. This would be about 72% of the yield indicated by the drill-holes previous to the 15% reduction, mentioned in Mr. Rolker's report. It should be noted, however, that all of the ground has not been dredged, and it is only when the property is worked out, that the actual recovery of the gold assumed to be in the ground will be ascertained. If the dredges of the Natomas company have been operating in its best ground, then a lower percentage of recovery than that stated will be obtained for the total ground handled. The dredges of the Yuba Consolidated have handled over 100,000,000 cu. yd. to February 1913. The actual recovery as compared with that estimated is not yet ascertainable, but, according to a large shareholder, it figures about 75% of that indicated by prospecting. Final figures will be interesting, as the Company has never been advertised; the stock is privately held; and it is the most productive gold dredging company in the world, over $8,000,000 having been paid in dividends.

The California dredges of the Oroville Dredging company have handled nearly 47,000,000 yd. to January 1914. At the time when the property was floated in London there were estimated to be 38,500,000 yd. with an average content of about 17.2c., and the Bear River property was stated to contain an average of 12c. The prospecting results as indicated by drill-holes on some of this ground had been discounted, previous to the consolidation, but evidently not on the larger part of the property. The average recovery from dredging 44,800,000 cu. yd., exclusive of Bear River gravels, was 11.17c. per yd., a recovery of approximately 65 per cent.

The Bear River area was even more disappointing. The average from 1,832,586 yd. during three years was 5.26c., or about 44% of the estimated content. The recovery made by the Pato dredge, operating on the holdings of this Company in Colombia, have been the subject of considerable comment, as the yield has been at times far in excess of the average gold content as estimated for the entire area. It is clearly understood by those with experience in such matters that the recovery made by a dredge over short periods often varies greatly. Discrepancies of recovery over such periods compared with the average gold content assumed for the whole area are worthy of no more importance than should be given to a few high drill-holes as compared with the average of the property, other than, perhaps, to indicate a richer spot or 'channel' in the area. That is, because the recovery from a property for a short period in the beginning of operations is higher than the average for such property, there is no reason to expect the whole area to exceed the average assumed.

Results at Pato

The results from Pato at this writing show that 750,000 cu. yd., yielding an average of 62.4c., have been dug in an area of 92 acres, which were estimated to contain a total of 3,780,000 yd. having an average content of 40.4c. While the recovery of the dredge, per cu. yd., has been 54% above the estimated content, as indicated by the drill for the whole 92 acres, this only means that the dredge is operating in the richer portions of the 'tested area.' No comparison of recovery as compared with prospecting content can rightly be made until a much larger part of this area is exhausted.

It has been stated[2] by the Colorado Gold Dredging Co., operating in Colorado, that the recovery from its dredge under the best conditions averaged about 80% of the gold previously estimated to be in the gravel. Other Colorado companies, however, did not succeed in obtaining as high a recovery. In fact, a number of the earlier dredging ventures in Colorado proved unprofitable, though doubtless the gold content assumed to be in the ground was sufficient to justify the business.

While the tests mentioned have been figured from prospecting done under the direction of careful engineers, there are numerous instances, particularly of early drillings, where the recovery made by the dredge has been 40% or less of the assumed average gold content of the ground. The dredges of one California company handled 8,156,571 cu. yd. and obtained a recovery of 40.6% of the gold indicated by prospecting.

At times, a poor recovery is made by a dredge on account of careless or inexperienced work during the examination. One company in West Africa, where the bore-holes indicated from 5 to 13 grains per cu. yd., never recovered more than 2 grains per yard.

Mention may also be made of a property near Nome, in Alaska, where less than 20c. per yard was recovered from gravel that it was claimed would average over $1. It is needless to say that this was not so much a case of poor recovery, as one either of poor prospecting or fraudulent representation. What was needed here, and

[2] 'Dredging at Breckenridge, Colorado,' by A. H. Bradford and Roy P. Curtis, *Mining and Scientific Press*, September 11, 1909.

would be valuable under like conditions, is not so much a factor representing dredge recovery as one to discount vendors' statements.

Some of the ground dug during the early stages of dredging will undoubtedly be re-dredged at a profit in the near future, when lower operating costs are made possible by increasing the dredge capacity. It is probable that dredges with a bucket capacity of 24 cu. ft. will some day be used to advantage in gold dredging as they are now used in harbor work, as discussed in my paper, 'Present-Day Problems in Dredging,' read before the American Institute of Mining Engineers at the San Francisco meeting in 1912.

Some ground that was re-dredged in California in moving boats to new positions returned from 1 to 3c. per yd.; not sufficient to pay operating expenses, but from one area a dredge recovered 10c. per yard when working through tailing. This led to an investigation, and the re-dredging of a considerable part of the tailing at a profit. Imperfect washing of the material due to the poor arrangement of the washing-plant and gold-saving tables, and perhaps the desire to make yardage records with the earlier dredge, was the cause of the poor recovery in this instance. In other cases where the gravel contains much clay or cemented gravel, the recovery of gold may be low and the tailing show sufficient gold to make re-dredging practical.

In northern California, the recovery recently made by a dredge was 15c. per yd. when working through the tailing from a dredge which formerly worked on the property. The reason for this was that the earlier dredge had not reached bedrock. The first dredge did not prove a financial success, but the second has been a profitable venture from the beginning.

The following table, prepared by one of the most careful California operators, is of considerable interest, and is based upon the following data: In dredging the property, it was found frequently that there had been a drill-hole at or near the centre of the ground dredged during the clean-up period of 15 days. In that case, the recovery was compared with the content indicated by the drill-hole. If a hole was reached at or near the end of the clean-up period, an average of two clean-up periods would be used as the recovery figure for comparison with the content indicated by prospecting.

It is shown in this case at least that a single drill-hole cannot be regarded as representative of the actual gold content of the surrounding area. This has also been the experience of other operators. In one case, when dredging where the drill-hole indicated 2.58c. per yd. as indicated on the table, the dredge recovered 15.5c. or 600% of the content given by the drill-hole; in another, from ground where the drill showed a content of 59.8c., the dredge recovered 20.7c. or 34.6%; and in a third, where 26.2c. was indicated only 4.6c. or 17.5% was recovered.

Any estimate to be at all trustworthy can only be made from the average of the content indicated from a number of drill-holes that have been intelligently placed and carefully sampled. If the work of prospecting has been done properly, an estimation of the gold content of a property can be made with some degree of accuracy, but if the work has been carelessly performed by unreliable or inexperienced engineers, the results obtained will be so worthless as to render any refinement of calculation merely ridiculous.

TABLE OF COMPARISON, SHOWING DRILL-SHEET VALUES AND ACTUAL DREDGING RESULTS AT OROVILLE, CALIFORNIA

(Arranged in order of highest drill-sheet results and reduced to percentages of recovery.)

Holes.	Drill-sheet value.	Actual dredge value.	Per cent recovered.

Three sets of drill-sheet figures are given as per results obtained by different engineers, 'A,' 'B,' and 'C.'

Where holes are designated alike on any two sets of figures it means a hole was drilled to check a former result.

All check holes drilled by 'C.'

New Reliance Mill Practice, With Particular Reference to Continuous Decantation

By JESSE SIMMONS

At the New Reliance property, in the Black Hills district of South Dakota, is the first plant that made a success of fine grinding on Bald Mountain ores. It is also the only mill in the district treating slime without agitation, and it was the first to install and operate the continuous decantation, counter-current system. A pioneer in a new field—the mill was started in August, 1912—the manager, F. C. Bowman, has solved numerous problems, and by constantly seeking to improve, has evolved a mill practice that is second to none in treating the refractory silicious ores of the Bald Mountain district. At the time this mill was started, there were but one or two others in the United States working along similar lines. The idea had been worked out on paper, but every metallurgist knows to his sorrow that ideas on paper and mill-runs are two separate and

NEW RELIANCE MILL.

distinct matters. So Mr. Bowman had to work out his own salvation, excepting that occasionally he heard of difficulties overcome at the other mills. The process as it is working today is about as follows.

The ore supply, amounting to about 100 tons per day, first passes through a gyratory crusher, is then elevated to bins, and is fed to the thirty 1000-lb. stamps, which operate in single-issue mortars. The stamps drop 96 times per minute, a distance of 7 in. Two sizes of screens are used, both of Tyler ton-cap pattern. One is No. 538, with an opening of 0.025 in., and the other is No. 423, with an opening of 0.024 in. The dies are made by Hogarth, at Deadwood, of old chrome steel and scrap iron. These give about 60 days' service. The shoes are of chrome steel, purchased in the East. The ore is particularly hard, silicious material, and is crushed fine, accounting for the rather low stamp-duty, which is a little over three tons per day. The ore contains no free gold. At the stamps, cyanide solution in the ratio of 6 tons to 1 ton of ore is added.

From a Dorr duplex classifier to which the stamp product flows direct, the sand, amounting to 40% of the product, goes to leaching vats, which are served by a revolving distributer. When there is about two feet of sand in the tank, the filtrate runs clear and percolation is started, the solution as drawn off going to the precipitating boxes. About 50 to 56 hours is required to fill a tank. Mill solution is then run on for two to three days, or until the gold content of the filtrate is too small to give good precipitation. After this the tank is drained fairly dry and barren solution run on, and a percolation with it kept up for three to four days, thus getting all of the recoverable gold. Treatment is completed by a wash with water, which, like the barren solution, goes to the mill sump. Sand tailing as discharged carries 24% moisture and an average of 2 to 3c. per ton of dissolved gold.

Slime Treatment

Slime from the Dorr classifier goes to a 20-ft. cone, from which the clear overflow solution goes to the mill sump, and the underflow, containing about 70% moisture, is run to thickener No. 1, the first unit of the continuous decantation system. At this point the pulp is united with the clear overflow from thickener No. 2, effecting a dilution of about 3 to 1. Ordinarily the overflow solution from this first thickener goes to the mill sump, although if there is a scarcity of precipitatable solution being drawn from the sand vats then being leached, it is diverted to the zinc-boxes. The thickener tanks are 4 in number, 3 of them 20 by 13 ft. and the other 20 by 10 ft. Each is equipped with a Dorr thickener. They are so placed that the solution runs from one to the other by gravity; the slime pulp is lifted by diaphragm pumps. Thickened pulp contains 60 to 65% moisture.

With a slight modification from the style as delivered by the manufacturers, these pumps are giving highly efficient service. The change made consisted of lengthening the standard, or rod, about four feet, thus permitting the removal of the pump jack that distance from its ordinary position alongside the pump, where spattering slime caused excessive wear on bearings and gears. Diaphragm pumps, so operated require almost no attention; their upkeep, aside from the diaphragms, is trifling; power consumption is so small as to be almost negligible; and, finally, they deliver a thicker product than air-lifts. Altogether, Mr. Bowman is well pleased with their operation, and is careful to point out that through their use an important sum is saved monthly in power consumption.

They are operated at a speed far in excess of ordinary practice. But at a speed of 26 to 55 strokes per minute they give good service. On 4 pumps in 12 months there were used 30 diaphragms, costing about

$2 each. Much depends upon the quality of the diaphragms; the highest and best grades of rubber have been found to give the best service at the lowest unit of cost.

Control of the duty of the pumps is effected by opening or closing a pet cock on the suction. There not being any convenient method of changing the speed of any particular pump, this scheme was tried and found to work perfectly: Using a 'T' in place of an elbow where the suction pipe makes a right-angle turn to connect with the pump, a bushing is placed in the upper branch of the 'T' and the pet cock screwed into it. The pump's duty is cut down by opening the cock. Some such regulator is necessary where the pumps must be operated at constant speed.

Operation of Portland Filter

Completion of the slime treatment is made on a 12-ft. diameter by 7½-ft. face Portland revolving drum filter, where the solution is drawn off, a little wash water added, and finally discharged with a moisture content of 36%. This might easily be made much lower, but if any thicker the slime would not readily flow to the dump. From the last thickener in the series the slime runs by gravity to the filter-tank, and in order to prevent it from settling in this tank, it is circulated once every 8 hr. with a diaphragm pump. Dissolved gold in the slime tailing from the filter, under normal conditions amounts to from 2 to 5c. per ton of dry slime.

For simplicity of operation, low cost of maintenance and repairs, the revolving drum filter is giving good results at this property. Under ordinary conditions, the cake made is $\frac{3}{16}$ to ¼ in. thick, and, as has been noted, could be drawn off with a much lower moisture content if it was desired to do so. Repairs are practically *nil*. They are to cloths, wire, and strips, a full set of which, giving the filter an entire new cover, costs about $27. From them is secured a service of from four to six months, handling 1200 to 1500 tons of slime per month. About the only other wearing parts are the worm gear and the scraper. In 22 months one renewal has been made of each of these parts, the gear costing $19.90 and the blade costing $4.50. In the same length of time there have been 5 changes of cloths—using 5 cloths, 5 sets of strips, 5 sets of wire, and 2 burlaps. These supplies, with the worm gear and scraper blade, are all that have been used, and the total cost of the whole was $150. Since 26,400 tons have been filtered, the repair cost was $0.00568 per ton.

To put on a new cloth requires about 20 hours, during which time 3 men are used for 8 hr., 2 men for 5 hr., and 1 man for 7 hr. Not over ½ hp. is required to operate the filter at its regular speed of 1 revolution in 3 min. In addition there is a 7 by 6-in. vacuum-pump and a 4½ by 4½ air-compressor supplying 11 cu. ft. per minute. The pump at 76 strokes per minute supplies a 15 to 17-in. vacuum.

No additional labor is required to operate the filter, as with some other types; it is practically automatic. Aside from regular inspections, and the occasional repairs and acid treatment, it runs itself. It might be mentioned that the slime does not contain any colloidal material. On the other hand it is, even in minutest particles, somewhat gritty and sandy. This fact, no doubt, has some bearing on the service obtained from the filter. Both the thickness of cake and length of life of the cloths probably would be different with material containing much alumina and clayey matter.

Tests on Settling Rate

Tests have been made to ascertain the settling rate of slime of various characters, as determined by screen analyses. It has been found that slight amounts of sandy material (larger than 200 mesh) have decided effects on the work of the thickeners. Taking 50 grams of dry ore, adding 200 c.c. of solution, placing in a 300-c.c. graduate, given enough agitation to get the mass

TAILING LAUNDER.

thoroughly mixed, the settling rate was noted in terms of clear solution settled out at various intervals. In the following table are given the amounts at the end of 5 and 30 minutes:

No.	Mesh −60+100.	Mesh −100+200.	Mesh −200.	Clear solution settled at end of 5 min.	Clear solution settled at end of 30 min.
	%	%	%	c.c.	c.c.
1	6	29	65	78	164
2	5½	27	67½	72	161
3	5	25	70	72	156
4	4½	23	72½	66	158
5	4	21	75	60	158

It will be noted that the extreme variation of the sand in these samples was but 2%, and of the slime 10%, but that the settling rate of the first 5-min. period showed wide differences. Not so great a difference is apparent at the end of 30 min. Screen analyses of material actually being handled in the mill give an idea, also, of the effect of the fine sand on the ability of the thickeners.

A material with 3.3% +100, 11.7% +150, 10% −200,

and 75% −200 mesh gave a muddy solution overflow from the thickeners, and a material consisting of 1.9% +100, 15.4% +150, 9.6% +200, and 73.1% −200 mesh gave a clear solution overflow. In these cases the sand, or +200 mesh, varies only 1.9%. Similar ore was going through the mill in the two cases cited; all conditions were apparently the same, but this slight difference in the percentage of sand was enough to mark the difference between satisfactory and unsatisfactory work. In this connection it might be mentioned that on a slime of the analysis given in the table herewith, containing 63% of −200 material, excellent work is done, with plenty of clear solution overflowing from all of the thickeners. Naturally, the underflow from the thickeners shows a variation in moisture content; when the effluent solution is clear, the moisture content is low; when the effluent solution is muddy, the underflow will contain a high percentage of moisture. This is a vital point, as the process of continuous decantation and counter-current solution system depends upon the thickeners yielding an underflow with a minimum of moisture; this means that the gold-bearing solution is to a satisfactory degree being replaced by barren solution.

Miscellaneous Data

Mill solution has a strength of 0.9 lb. KCN and 1.8 lb. CaO per ton. Consumption of cyanide is 0.3 lb. and lime 10.75 lb. per ton. The cost for mining and milling, from August 1, 1913, to February 1, 1914, on handling 11,677 tons of ore, was $3.04 per ton.

For acid treatment of the filter, there was used during 22 months 1250 lb. of commercial HCl, costing $58, or $0.0022 per ton. Power used is about as follows: 30-hp. motor on crusher, 11 kw.; 3 motors of 25 hp., each driving 10 stamps, 18 to 20 kw. each; 1 hp. on classifier, 0.36 kw. Everything that has to do with slime department, including filter, thickeners, vacuum-pump, compressor, diaphragm pumps, and solution pumps, is driven by a 20-hp. motor consuming an average of 10.25 kw. Water supply is secured by pumping from wells and springs, using one 5-hp. and one 3-hp. motor, consuming 2.5 and 2 kw., respectively.

There is ordinarily precipitated in the zinc-boxes two to three tons of solution to each ton of ore milled. In this connection it might be stated that no clarifying filter is used prior to precipitation. Several months ago the solution men were offered a bonus of $2.50 per month, each, if during a month no ore slime found its way to the precipitation boxes. A fine of $1 is imposed on the man allowing it to happen. With three solution men it has cost $7.50 per month, but is money well spent, as there has been no ore slime in the precipitating department for six months. This system is probably just as efficient as a filter, does not cost much, if any, more, and gives the men a moral lesson in watching not only this matter, but others of importance. The entire mill is operated with a crew of 8 men, namely, cyanide foreman, crusher man, 3 battery men, and 3 solution men.

Tailing Disposition

Situated at the head of Annie creek, which drains into Spearfish creek, it is necessary to impound the tailing so that none shall escape into the latter stream. A dam 160 ft. long and 50 ft. high in the centre has been constructed at a narrow point in the gulch half a mile below the mill. The face of this dam is composed of two thicknesses of 2-in. plank with a single thickness of tar-paper between. The plank is laid on 4 by 12-in. and 3 by 12-in. joists, which rest on a heavy frame of 8 by 12-in. and round peeled timbers. The latter material is used for all mud sills and cribbing. The face of the dam has a slope of 37 degrees.

This serves as a settling dam, and over the apron the overflow is practically clear. Sand tailing from the mill is carried in a wooden box launder to a point in the gulch 200 yd. above the dam, where the launder is turned directly across the gulch, dumping the sand in an embankment forming a dam to hold back the slime. The launder, a view of which is given in Fig. 2, is constructed of 6-in. and 8-in. boards, forming a box 6 by 6 in. inside. For a portion of the distance immediately below the mill, the launder is set on a grade for 9.5 in. in 16 ft.; the remainder of the distance to the turn across the gulch, the grade is 11.5 in. in 16 ft., and crossing the gulch the grade is 12 in. in 16 ft. Although these figures indicate a light gradient for a launder to carry sand, it works to good advantage.

Screen Analyses, New Reliance Mill

Mesh.	Battery discharge.* %	Filter heads. %	Sand. %
— 20 and + 40	8.4	...	40.7
+ 60	13.8	...	18.7
+ 100	17.9	5.7	25.2
+ 150	17.9	22.8	10.5
+ 200	8.2	8.5	1.6
— 200	33.8	63.0	3.3
	100.0	100.0	100.0

*This is separated by classifier into 60% slime and 40% sand.

The Amalgamated Zinc (De Bavay's) Co. of Broken Hill reported that during the half-year ended June 30, 1914, the flotation plant treated 247,386 tons of tailing for 69,918 tons of concentrate, assaying 48.6% zinc, 6.1% lead, and 8.9 oz. silver; also 687 tons of lead concentrate, containing 53.5% lead, 53.1 oz. silver, and 14.1% zinc. This is a small decrease compared with the previous term. Including adjustments on previous concentrate produced, the profit was $297,000. Owing to the war, contracts for the sale of products were suspended, but some arrangement has been made for final settlement with the buyers.

Manganese ore shipped from the Brazilian port of Rio de Janeiro during 1912 amounted to 154,870 metric tons, worth $7.22 per ton. Since the end of that year no ore has been sent from Bahia. Cost of mining, transport, lighterage, export duties, etc., is $2.80 per ton in the state of Bahia.

Thomas Johnston Grier—A Pioneer Mine Manager

Thomas Johnston Grier, superintendent for the Homestake Mining Company, at Lead, South Dakota, died at Los Angeles, California, September 23, 1914, at the age of 64 years. The cause of his death was stated to have been valvular leakage of the heart. He was born at Packenham, Ontario, Canada, where he received his early education, his school days not extending, however, beyond the course of the high school of his native town. Upon leaving school he was appointed deputy in the post-office at Packenham where his father was postmaster. While thus employed he took up the study of telegraphy, which was at that time a comparatively novel occupation, and whose mysteries had invited his attention promptly. In a few months he had advanced sufficiently to secure an appointment as operator in an office at Montreal, Canada, where he became one of the most rapid as well as accurate operators in the Dominion. The call of the West reached him in his Canadian home, and he went to Corinne, Utah, on the line of the Central Pacific railroad. Corinne was at that time a prosperous and typical frontier town, and he thus early came in direct contact with the rapidly shifting, cosmopolitan, and somewhat unruly element of the West, and so gained a knowledge of men from many classes and nationalities, which experience in later years was to be of great value to him in directing the work of thousands of employees, many of whom were foreigners, and not always the most tractable.

A Telegraph Operator in Utah

His work as telegraph operator at Corinne was so satisfactory that he was transferred to the Salt Lake office of the Western Union, where he was placed in charge. It was at Salt Lake City that he made the acquaintance of George Hearst, who was prompt to recognize the executive ability of the young chief operator, and in 1878 sent him as head bookkeeper and telegraph operator to the Homestake at Lead, South Dakota. Grier arrived at the Homestake when it was still a comparatively small enterprise. The construction period was just beginning. The first Homestake mill of 80 stamps was built in the summer of 1878, and the Golden Star and Highland mills of 120 stamps each followed soon thereafter. The other great mines of the 'Homestake belt' were being developed, mills were under construction or were being planned, and large shafts were being started. Samuel McMasters was then superintendent at the Homestake. He was a big, brawny Scot, inured to hardship, a hard worker, with experience gained on the Comstock. He was a commander of men, but a peculiar combination of hard, practical sense, inflexible fidelity to his employers, and of ruthless disregard for personal friendship if it in any way interfered with the interest of his company—a good organizer and executive. He planned far ahead, for those days, and, foreseeing its necessity, built a narrow-gage railroad 50 miles in length out into the timbered region of the Black Hills in order to supply the demand for timber and fuel. He also acquired about all of the water available by gravity, and began mining at the Homestake on a large and ever increasing scale.

During all of the years of activity, Thomas J. Grier familiarized himself with every portion of the property, and with every phase of its operation, literally growing up with the business. He was nominally head bookkeeper and was well known and recognized in the community as a genial though rather quiet man. He was always courteous but never brusque; in this respect differing from McMasters, who on occasion could be pleasant or quite otherwise.

Superintendent of the Homestake

The heavy responsibilities of the conduct of the large and constantly increasing business of the Homestake company undermined the constitution of the big Scotch manager, McMasters, and failing health necessitated several vacations in the early '80s. These extended over periods of several months. During these absences, the responsibility for the operation of the mines devolved upon Grier, who performed the duties to the full satisfaction of his employers. In 1884, McMasters, whose health had continued to fail, passed away, and many wondered who could be found to assume the duties of the position left vacant. To the surprise of many, the Homestake mills did not hang up a stamp. The announcement of the name of the new superintendent was looked for with much interest by the mining communities of the Black Hills, but no announcement was made. Grier was not prominently mentioned, but he continued to discharge the duties of superintendent, just as he had during the several periods of absence of its late chief executive. A year or more passed, Grier acting as superintendent the while, yet modestly refraining from assuming the title of manager or even of superintendent. One day in conversation with the late G. C. Moody, who was then attorney for the Homestake company, Grier brought up the subject of the superintendency of the Homestake mines, and Moody suggested that as Grier was acting in the capacity of superintendent, he not only assume the title, but take the emoluments of the position as well; which Grier accordingly proceeded to do. On the recommendation of Grier, other properties on the 'Homestake belt,' as it is known, were acquired by the Homestake company, until this concern became the owner of a tract of mineral land over 2000 ft. wide and about two miles long. The great mills of the early days were enlarged, until there were six containing in the aggregate 1000 stamps. These have crushed more than 4000 tons of ore every 24 hours for many years. Six large shafts were sunk to hoist the

ore and to handle the men and supplies; two large cyanide plants were built after a long and costly series of experiments conducted by C. W. Merrill and his assistants, and later a third and still more expensive plant was added to treat the slime. A great new water system was planned and built whereby water is pumped over a mountain from the cañon of the Spearfish river and sent to the Homestake mills, and to the cities of Lead and Deadwood. Improvement after improvement, one expansion after another, was made. The Company now employs in all over 3000 men. Only mining men can understand and appreciate the magnitude of this enterprise, with its miles upon miles of underground workings, its great mills, its problems of transportation, and the vital matter of a never-failing water supply for the mines and for the inhabitants of the cities of the vicinity. Notwithstanding the magnitude of the operations of the Homestake company, Thomas J. Grier was thoroughly familiar with every detail, and knew the ramifications of the mines as a man knows the passages and rooms of his own home. In the early years of his career as superintendent it became evident that improvements in mining methods were desirable. The great timbered stopes were unsafe, some of them having already caved. Grier surrounded himself with a staff of competent engineers and experienced, capable, practical miners, and a period of evolution in mining practice at the Homestake began. Change after change was made where it seemed an improvement could be introduced. He invited suggestion from the men and made many far-sighted and valuable ones himself. New ideas were tried out and adopted or rejected as they proved to be betterments or the reverse. Grier never thought that men were cheaper than timbers, and no expense was spared to render the operation of the mines of the Homestake company safe and sanitary, and it is a matter of note that under his direction the percentage of accidents steadily decreased as newer and better methods of mining were introduced.

Thomas J. Grier was a man who fully sympathized with his men. He was a personal friend and adviser as well as a superintendent. Through his efforts the city of Lead has splendid schools, a fine library, first-class sanitary arrangements, paved streets, a model fire department, and in many respects came to be a model mining town.

Homestake Fire

The duties of superintendent, arduous as they were, were at times greatly increased. On the evening of March 25, 1907, the city of Lead was startled by the ringing of the fire bells, and soon the dreadful news spread throughout the town that the Homestake was on fire somewhere on the lower levels. When discovered, the fire was beyond control, and the great volumes of carbon dioxide being generated by the fire made it impossible to approach anywhere near the seat of the fire. Grier arrived on the scene within a very few minutes of the first alarm, and every effort that experience and skill, backed by heroic courage, could make was tried to extinguish the flames. It soon became apparent that ordinary methods were fruitless. Scores of miners ventured into the mine only to fall fainting in the poison-laden galleries, whence they were dragged to safety by companions. For a week Grier fought this fire, and then ordered all men out of the mine workings, having decided that it was useless to attempt further to fight the fire in the mine workings. Small streams of water were sent down into the mine through various shafts and open workings, but the fire still gained headway. Finally, on April 22, Grier decided to apply heroic measures. He ordered the water of the entire canal system turned into the mine, over 1500 ft. in depth with several miles of levels. A flume over 3000 ft. in length was hastily built in the cañon of Whitewood creek and nearly all of that stream was also turned into the mine through an old adit. In this way over 500,000,000 gallons of water was poured into the burning mine, the streams never stopping until the water appeared at a drainage adit. It was then known that the fire was submerged and must, of course, be out. Then began the work of unwatering the workings. It took months to accomplish this, but it was finally done, and the damage to the mine was found not to be very great, as the mining had been so well done that few serious caves occurred. During this interval, Grier took advantage of the enforced idleness of the mine to make various changes that he had long contemplated, but which he could not very well carry out without interfering with regular operations. These changes, when completed, reduced still further the expense of mining by reason of increased efficiency, and when the workings were finally unwatered it was in better condition for operation than ever before.

Labor Trouble

Although in the matters pertaining to the policy of the Homestake Gold Mining Co. toward its employees and toward the communities that had grown up about it, the superintendent had the fullest authority, and in the exercise of this power Grier had been almost parental in his humane and kindly treatment of the men in the things that most concerned them socially as well as in in the mine, yet there was a time when all of his painstaking care of their interest seemed to be almost wholly unappreciated. As early as 1878 a miners' union was organized at Lead, with branches at Central and Terraville, small towns on the lode. Nearly all the miners were members of one or the other of these unions. The objects of these organizations were fraternal and beneficiary. Wages were as high as were paid in the West for mining, and working conditions were as good as at the best, and superior to most others. The unions were conducted in a fair and friendly manner, and for over 30 years prospered under the direction of wise and conservative officers. Here the miners had their homes, here their children were born, and here they expected to remain. There were good schools, a clean city, and there had never been a moment's anxiety about pay day, for their checks were always ready as sure as the day ar-

rived. There was perfect harmony between the miners' union and the superintendent, who aided it as an organization in various ways. All went well until the arrival at Lead of agitators of the Western Federation of Miners in the fall of 1909. An active and somewhat belligerent campaign was started to gain a foothold in the Black Hills. So aggressive were these officials of the Western Federation that by November of that year they had succeeded in gaining a large membership. They then felt strong enough to make a demand that all miners not already affiliated with them join within a specified period or take the consequences. The records of Cripple Creek and other districts where the Federation was in power indicated only too plainly what those consequences might be expected to be.

When things had reached this condition, Mr. Grier could no longer safely ignore it. This was his first serious labor trouble. A very large percentage of Homestake employees had either voluntarily or under duress joined the Western Federation. With characteristic fearlessness he issued a notice to the effect that after January 1, 1910, the Homestake company would employ only non-union men: that the same scale of wages as previously paid would be continued, the shift being 8 hours; and that anyone who desired to secure employment must declare that he was not a member of any union and must register his name in the Company's books by December 15, 1909. It took courage of no unmistakable kind to issue an ultimatum such as this, but Grier was equal to just such an emergency. He felt that the Homestake company had dealt fairly with its men for over 30 years and that it had not only done all that it should have done, but more, and he accordingly resented vigorously this outside interference.

Breaking the Strike

The effect of the publication of the notice above referred to was electrical. It had been unexpected. The strangers who had worked up this interesting situation felt so strong that they were sure the superintendent of the Homestake company, seeing the vast majority against him and the great amount of property at stake, would quietly submit to the inevitable, but they did not know the fighting spirit of Thomas J. Grier. Upon the appearance of the notice, the Federation officials waited upon Grier for the first time, and with loud and threatening talk tried to coax, wheedle, and bully him into coming to their terms. They 'laid down the law' to him and demanded to know what he meant by the publication of the offensive notice. Grier informed them that it meant exactly what it said and that it would not be modified in the slightest degree. They blustered and threatened, pointing out the fact that an overwhelming majority of his workmen had joined the Western Federation, and that only loss and peril awaited his opposition. All of this Grier quietly ignored, and as a result the Federation officials, at a meeting on November 21, 1909, declared a strike against the Homestake company, to become effective as soon as their action could be ratified by the Denver headquarters.

Grier anticipated them by 24 hours, for on that evening no night shift went on and men were laid off by the hundreds. A comparatively small crew of faithful employees worked, removing the machinery and other readily movable and perishable paraphernalia from the mine workings, and the great mine was idle—the shutdown was complete. Guards were employed to protect the property and the town waited in silence the outcome of the battle. The Western Federation published the names of 49 of the men who stood by the Company. This was another boomerang, and led to the organization of a new association called the 'Homestake Loyal Legion.' In three days hundreds of men had signed the Company's register and soon the number was over 1000, all of whom joined the Loyal Legion. Not only miners, but merchants and professional men became members. Public opinion was decidedly opposed to the Western Federation and in favor of Grier, who for more than 30 years had proved his worth as a citizen and friend. Within a week the Western Federation had lost its cause and soon the great mines and mills were running at full capacity as though there was not a Federation in existence. The following summer a new organization was formed by the Homestake company called the Homestake Employees' Aid Fund, to which both the men and the Company contributed. Grier was elected treasurer of this organization by the men, which showed how highly they regarded him as a true friend.

The death of Thomas J. Grier has taken away a man who cannot easily be replaced. Another and capable superintendent has been found, but it will be long before he can take the place of Grier in the minds and the hearts of the men of the Homestake mines. He was most loyal to his friends, and particularly to those who stood by him in the hours of trial and danger, when fire was destroying and civil war was imminent. He was always just but firm. He considered all problems affecting the welfare of the men under his direction with seriousness, and having determined upon the proper course adhered to it. His loss will be mourned by thousands of men throughout the mining world.

A large colored wall map, showing the petroleum resources and the natural gas deposits of the United States and also the thousands of miles of trunk oil pipelines, has just been printed by the U. S. Geological Survey. The map shows the areas underlain by known oil pools and known gas pools, as well as general localities which are productive in either oil or gas, and also areas where there are noteworthy occurrences of either oil or gas but where there is no present production. The map is 49 by 76 in., printed on the scale of 40 miles to 1 inch, in 5 colors. It is printed in two sheets and is sold, unmounted, by the Geological Survey, Washington, D. C., at $1 per copy. This map not only shows graphically the oilfields and pipe-lines, but is an excellent general map of the United States.

No cobalt, molybdenum or nickel was produced from domestic ores in 1913.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Flotation and the Patent Law

The Editor:

Sir—In an editorial entitled 'Flotation and the Patent Law,' appearing in the *Press*, issued October 17, 1914, a digest of an address delivered by James M. Hyde, before the San Francisco session of the American Institute of Mining Engineers is given, which credits me with two statements which do not exactly represent what I intended to state.

I am there quoted as giving as one of the reasons why the present legal procedure in patent cases should be changed, that "the judges are not capable of understanding the technicalities of inventions and disputes arising over them." I did not intend to make any such general statement as this. While many patent cases involve questions of such technical detail that it is too much to expect the judge with non-technical training to comprehend all that is involved, justice to our present judges demands recognition of the fact that through their decisions certain of them have shown that their comprehension of involved patent issues is very acute. Such a patent court as was suggested as more advantageous than the present practice of having the federal court pass upon these matters could well draw several of its members from the present federal bench to sit with other judges selected principally for their technical qualifications.

Referring to the work done by the Butte & Superior Copper Co. during the first half of 1914, the statement is made that "the total milling cost was $2.02 per ton of ore, of which Mr. Hyde estimated the flotation cost as between $0.50 and $0.60 per ton." The milling cost of $2.02 per ton is that announced by the Company in its reports, no analysis being given of the items making up this total cost. In the address it was stated that the original investigation made upon this ore at a time when water treatment alone was costing $1.50 per ton, indicated that additional costs for flotation concentration in the plant at that time being used at Basin, Montana, would probably be between $0.50 and $0.60 per ton, and that it was interesting to note that the total cost in the Butte mill, where various factors were different from those in the mill at Basin, had arrived at a total milling cost of practically that which had originally been estimated. The correction is offered, as no analysis of costs has been presented to the public, and it should not be understood that the statement referred to assumed that flotation costs at Butte are now $0.50 to $0.60 per ton, as the various items of cost of labor, water, etc., differ in the two plants, and the total undoubtedly is made up of somewhat different items than those taken into account in arriving at the preliminary estimates for the Basin plant.

James M. Hyde.

San Francisco, October 29.

Electric Power v. Mules in Coal Mines

The use of electric locomotives and mechanical devices is the only means by which the anthracite coal operators of Pennsylvania have been able to keep pace with the increased cost of mining due to thinner veins, longer hauls, and deeper shafts. It is only by increased efficiency in every department that modern mining can be made to pay. In the last decade, from 1902 to 1912, the horse-power developed at the mines increased from 354,237 to 680,700, or 326,463 horse-power.

By far the greater part of this increase was in transportation below ground. This was formerly accomplished almost exclusively by the patient mine mule. But a good mule is now worth $240. If this 326,463 additional horse-power had been added in mules, supposing such a number obtainable, the investment since 1902 in power alone would have been nearly $80,000,000, without replacing any mules that died during that period.

As a matter of fact, the number of mules decreased from 16,139 in 1902 to 15,187 in 1912. On the other hand, the number of electric locomotives increased from 53 to 951, and the number of steam locomotives on the surface from 373 to 575. For short hauls and steep grades, no adequate substitute for the mule has been found, except a gathering apparatus consisting of a rope on a reel extended from the electric locomotive; but on long hauls and moderate grades, steam and electricity are saving millions of dollars annually.

But the increase in other necessary forms of energy makes the problem of operating the mines at a profit one of careful selection of the most economical means. In 1912 the consumption of powder was 41,401,015 lb., and of dynamite 13,685,062 lb., in addition to 2,037,026 lb. of other permissible explosives. This is 1,128,335 lb. less of powder than in the busy year of 1903, but was 8,367,640 lb. more of dynamite, and no other explosives were used in that year. This increase of over 9,000,000 lb. in explosives, wholly disproportionate to the amount of coal produced, is largely due to the great amount of rock work which now has to be done.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

MINING COSTS at the Camp Bird mine, Colorado, during the past financial year totaled $5.12 per ton, a high charge due to small tonnage milled, a narrow vein, and hard rock.

CHINESE MECHANICS employed at the Shanghai Dock & Engineering Co.'s works in China, are quite satisfactory and receive 50 cents per day. The ordinary coolie is paid about $3.50 per month. This firm can compete successfully with Japanese shipbuilding concerns in bidding for contracts throughout the Far East.

CRAWL GIRDERS OR BEAMS should have an uninterrupted run from end to end of a battery-house, and every facility should be insured for executing repair work in the minimum of time and with the minimum of labor. Space and light are generally the cheapest of commodities. A badly laid-out mill building will cause more loss than is ever ascertainable.

DYNAMITE used in the mines of the Oriental Consolidated, Korea, amounts to approximately 4000 50-lb. boxes per year. Also 1,000,000 detonators. Government explosive regulations stipulate that only 250 cases of *fracteur* may be stored in each magazine, while special permission was obtained to keep 180,000 caps in each, both to be kept in separate magazines.

SOME of the German cyanide, as has been mentioned before in this journal, is manufactured from the residue of beet sugar. Growing beets for sugar has attained enormous proportions in Germany, especially in the Magdeburg district. There is a total of 1,342,420 acres under crop, and the last season's output is estimated at a minimum of 2,500,000 tons of raw sugar. At present there is 200,000 metric tons available for export, and probably 900,000 tons will be at a later date.

AFTER AIR ENTERS A MINE, the breathing of men and animals, burning of lamps, decay of mine timbers, and firing of shots take oxygen from the air and add carbon dioxide to it, but in well ventilated mines the air depletion from these causes is small. Much more important changes are those caused by oxygen being taken from the air by the coal; and by gases from the coal, the roof, and the floor being added to the air. The most important gas given off in many mines is methane, or marsh gas, which most miners call 'gas.'

GUN-COTTON, used in torpedoes, is made by treating cotton from spinning machines (cotton waste) with a mixture of 1 part nitric acid and 3 parts by weight of sulphuric acid. The contact is up to 12 hours, considerable heat being generated during the reaction, necessitating the vessels being surrounded with water. Excess liquor is removed from the treated material by a centrifugal extractor. The cotton is then washed in water suddenly to remove the remainder of the acid, further drained and washed, and reduced to pulp in a rag-engine as used in paper mills. It is again washed in warm water for about 48 hours, a little lime, soda, or ammonia being added to neutralize any trace of acid. The pulp is finally molded as desired, it containing a little moisture to avoid explosion during cutting, etc. When gun-cotton is enclosed in a strong case, such as a torpedo, and exploded by contact, rapid decomposition takes place, and Berthelot has estimated that the pressure produced by the detonation of the explosive, compressed to a density of 1.1, is 24,000 atmospheres, or say 160 tons per square inch, only half the pressure assigned by him to the detonation of mercuric fulminate.

QUICKSILVER is used mainly in the manufacture of fulminate for explosive caps, amalgamation of gold and silver ores, drugs, and various apparatus. Out of the 20,213 flasks produced in the United States in 1913, it is said that about 10,000 flasks are used for fulminate for caps. Fulminates are prepared by treating mercury with nitric acid and alcohol. In the first reaction, the solution contains mercuric nitrate, nitric acid, and nitrous acid. When all the metal is dissolved, the required quantity of alcohol is added. A brisk action results, and the fulminate separates as a crystalline precipitate. The fume from this action is very poisonous. The fulminate is collected, washed free from acid with water, and air dried. The salt or fulminate has a gray color, and explodes easily, giving off gray fume of mercury, as $HgC_2N_2O_2 = Hg + 2CO + N_2$. The specific gravity of the explosive is 4.4, and the gas and vapor from detonation would occupy over 1340 times the volume of the solid salt at ordinary temperatures. At the moment of detonation it would occupy a greater volume, on account of the heat evolved in its decomposition. It has been estimated that a pressure of 48,000 atmospheres (720,000 lb. per sq. in.) is produced. The explosive nature of the fulminate is due to its containing an oxidizing group, Hg linked to O, and a cyanide group, Hg linked to CN. In the manufacture of percussion caps the explosive force of the fulminate is lessened by adding potassium nitrate or chlorate. Powdered glass, or sometimes antimony sulphide, is mixed to increase the sensibility to explosion by percussion in military caps.

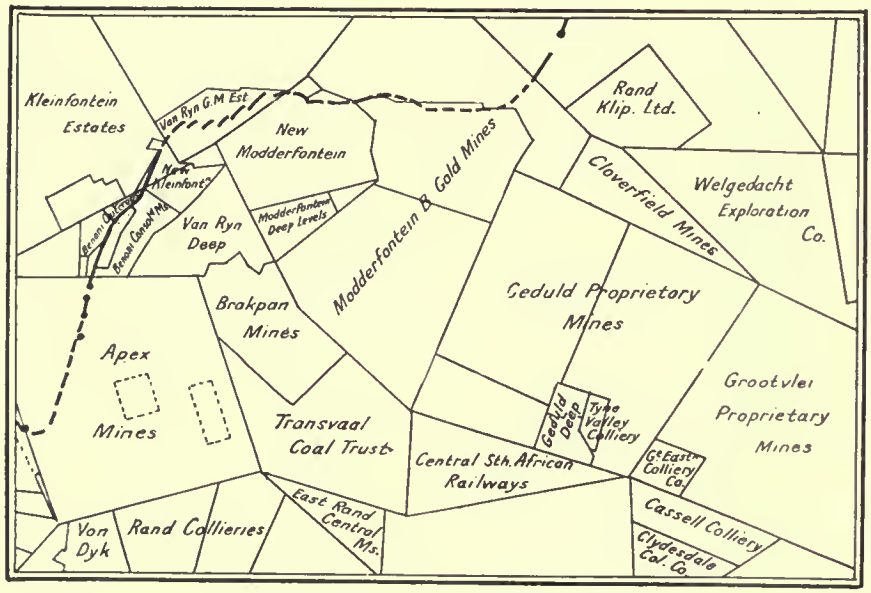
REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

GEOLOGY, DEVELOPMENT, AND PROSPECTS OF THE NEW MODDER, MODDER B, MODDER DEEP, AND GOVERNMENT GOLD MINING AREAS IN THE FAR EAST RAND.

At the present time, the group of mines in the far east Rand, usually included under the general name of the Modderfonteins, is attracting the chief attention among Transvaal properties. The banket in these areas has no outcrop, as the pre-Cambrian series containing it is overlain by coal measures and other deposits of later date. The beds are of basin shape, and the banket is supposed to have another outcrop on the ancient surface, but still covered with more recent beds, to the south and east. The chief evidence to support this supposition is provided by the Nigel group of mines in the Heidelberg district. Boring has been done extensively throughout this basin area, and only recently the results at the Daggafontein bore-hole were announced as indicating a banket deposit 4 ft. thick, averaging $8 per ton at 3500 ft. depth. Two mines at Modderfontein are large producers, the New Modderfontein and the Modderfontein B. Below them on the dip are the Modderfontein Deep Levels, and the Government Gold Mining Areas (Modderfontein). The first two belong to the Rand Mines group, the third to the Goerz, and the fourth to the Barnato. The two latter have been extensively developed, and their equipment has been so far completed that milling should commence by the end of the year. The New Modder is often called the greatest gold mine on the Rand at the present time. The actual area covered is not quite as great as that of the three great consolidations, Crown Mines, East Rand Proprietary, and the Randfontein Central; and as the dip is flatter the amount of 'reef' per unit of horizontal area is not so great. But the area is big, measuring 1.6 by 2.25 miles, the mine contains large reserves of high-grade ore, and the current developments are excellent. From a speculator's point of view, there are better prospects here than in the other properties. About one-sixth of the area has been stoped, and a similar portion has been developed. The remaining two-thirds remains to be exploited. Four incline shafts are in use, and recently a circular vertical shaft has been sunk at 2000 ft. from the southern boundary, and two levels opened there. Development was started as far back as 1888, and the first mill, of 40 stamps, commenced in 1896. It was not, however, until 1907 that the first dividend was paid. At the present time the metallurgical equipment consists of 180 stamps and 7 tube-mills, and has a capacity of 52,500 tons per month. It is intended to erect another mill near the circular shaft with a capacity of 40,000 tons per month. The ore developed recently is of higher grade than previously, and the reserve has been greatly increased. During the past 12 months the figures have risen from 4,351,000 tons to 5,913,700 tons, and the average content from $8.26 to $8.46. The profit, after allowing for every possible item of expenditure, is about $3.60 per ton at present, so that the total distributable profit that may be expected from the developed ore is $22,000,000. This does not include 420,000 tons of ore left as pillars, which under the modern system of stope-filling will be eventually reclaimable. During the past 12 months the revenue from the sale of gold was £990,354, obtained from 537,000 tons hoisted, of which £707,243 was won by amalgamation and £283,111 by cyanide. The amount of profit, that is to say, the dividends distributed, was £420,000. These figures go to prove that the New Modder is one of the great mines of the world.



CLAIM MAP OF MODDER GROUP OF MINES.

The Modder B adjoins the New Modder on the east, and is of only recent development, the Company only being formed in 1908. Milling started in 1911 with 80 stamps and 5 tube-mills, and the first dividend was paid 18 months ago. In the area close to the New Modder, recent work has disclosed ore of unusually high grade, as much as 585,000 tons averaging $12.50 per ton has been added to the reserve during the year 1913. The total reserve is now nearly 3,000,000 tons averaging $8.40 per ton. Unfortunately, the ground in the eastern portion is considerably faulted, and development is difficult. It is interesting to note that the extension of the mill put into operation this month consists of 16 Nissen stamps. This type of mill has won its way in Africa after unprejudiced competitive results.

As regards the other mines, the Modder Deep is on the dip of the New Modder. Shaft-sinking commenced in 1910, and by the end of June last nearly 2,000,000 tons of ore averaging $8.40 per ton had been developed. The plant contains 60 stamps and 6 tube-mills, and its erection should be completed by the end of this year. The method of development of the property is based on the German coal mining system, and the two shafts required by law for ventilation purposes are situated only 100 ft. apart. This property is a small one compared with its neighbors, and consists of a wedge between the New Modder and the Government Gold Mining Areas. A point in its favor with regard to the possibilities of future

development is that it is bounded on the west by the Van Ryn Deep, another mine of recent date that has a large and valuable ore reserve.

The Government Gold Mining Areas (Modderfontein) Consolidated, Ltd., is a Company that suffers from the folly of its godfathers in the matter of name, and the difficulty is to find a convenient colloquialism that will act as an efficient substitute. The Company was formed in 1910 to acquire property from the Transvaal government on terms not previously known on the Rand, though similar to those ruling with the Premier Diamond Mines, Limited. No cash purchase price was demanded, but the government asked for a share in the profits on a sliding scale, the maximum under present conditions being 40% of the distributable profits. Barnato Brothers were given the lease, after public advertisement of the terms, and it may be a curious coincidence or not, that the same firm has gradually bought control of the Premier. The property is to the south of Modder B and Modder Deep, and has the Brakpan on the west and the Geduld on the east. The area covered is more than twice as great as that of the New Modder. Four vertical shafts have been sunk, each measuring 42 ft. 6 in. by 6 ft. 6 in. and intersecting the banket at depths varying from 2275 to 3600 ft. On June 30 the developed ore was estimated at 1,800,000 tons averaging $6.48 per ton. The treatment plant, now nearly ready, contains 100 stamps and 10 tube-mills, and has a capacity of 600,000 tons per year.

The South African School of Mines, at Johannesburg, has been closed temporarily, owing to the number of students called out to join the defense force of the Union. Those students not so absorbed have been engaged by the Consolidated Gold Fields mines.

WASHINGTON, D. C.

Influences at Work on the Bill to Codify the Mining Laws of the Country.—First-Aid for Gas and Electric Shock.

It appears that considerable influence opposing legislation in Congress proposing the creation of a commission to codify the mining laws of the nation, is made up of men in the mining world who fear that such a commission may wish to revise the laws relating to apex mining, and fearing any tampering there they are opposing any codification whatsoever. It is felt by these that the apex laws, and the interpretation of them by the courts are now so well established and understood, that to revise them or to create new mining laws appertaining to extralateral rights might completely disorganize the present status of mining, and lead to great confusion until such a time as the courts could once more by their decisions bring order out of chaos. And apparently there is something to be said for this point of view. There has been some question why no progress was made in Washington in the late session, in the legislation purposing to create a codification commission, and it was generally attributed to the fact that the bill in the Senate carried an appropriation of $25,000 to meet the expenses of the commission; but it now seems that, although this has been a reason for the attitude by Congress, it has been but a minor reason, and that the chief one has been that provided by those who fear that a codification of the mining laws would also probably mean new laws bearing on the apex question.

There is this much to be said: the conclusions of the commissions would not necessarily mean that they would become law. The commission would be powerless to enact any laws. Its province would be only to recommend. The commission would report to Congress, which would refer the report to a committee, one in each house, or possibly a joint committee, and this, or these, in turn would draft a bill embodying as much of the recommendations of the commission as they chose, or rejecting its conclusions entirely or in part, possibly and probably substituting the ideas of the committees themselves, if in their judgment these are preferable. The bill would then have to run the gauntlet of both houses of Congress. And it would be a gauntlet indeed, as Congress always takes its time in passing bills codifying the laws of the United States, consuming usually therein months of the session, examining closely the contents of the bills and debating them thoroughly. As there are in Congress not a few members who are well posted in mining law, a thorough debate might be expected. No crude, radical, or ill-advised legislation could be expected from such a procedure. The mining world would, in addition, certainly be given an extensive hearing.

The committee of university authorities, headed by U. B. Cannon, professor of physiology at Harvard, has made its report to the Bureau of Mines, which appointed it, on what are the most efficient methods to be administered to miners overcome by electric shock or gas where a physician or surgeon cannot be reached in time to apply life-saving methods. In consequence, Joseph A. Holmes has recommended certain procedure in first-aid, which has been published in pamphlet form for distribution.

NEW YORK

Further Discussion on the Copper Situation and Export Trade.—Nevada Consolidated Report.—Minerals Separation Suits.—Tonopah Mining Co. in Nicaragua.—Peruvian Finance.—Antimony.—Society Meetings.

The situation in the copper market took a serious turn last week when the British government seized the Italian steamships *San Giovanni* and *Regina d'Italia* at Gibraltar, on account of the cargoes of copper consigned to Italy which they contained. The *Kroonland*, an American steamer, with 1300 tons of copper consigned to Italy, was detained as well. The result of this was that the Sicilian-American and Lloyd-Sabaudo lines have refused to take shipments of copper except under a guarantee by the shipper that the copper shall not be reexported from Italy, a guarantee which the shippers here, of course, could not give. Since exports of copper in the last week, which were fairly heavy, were more than half consigned to Italy, this is a serious state of affairs, and is likely to cut down exports by nearly half, unless some way out of the difficulty can be found. The State Department is considering making a protest, but no immediate relief can be expected. It is also reported that ships carrying copper to the Scandinavian countries have also been detained at ports in Scotland. The result of this is that England and France are practically the only countries to which American copper can now be shipped without fear of seizure. As a result, the price of copper is weaker than ever, and domestic buyers seem to be holding off in the expectation that it will go even lower. It will soon be impossible to obtain marine insurance on copper, unless the exporters can give a guarantee that the metal will be consumed in the country to which it is consigned. The destination of the consignments of copper made week before last is of much interest as indicating the direction which export shipments are taking.

Destination.	Pounds.	Destination.	Pounds.
Genoa	6,946,288	Christiania	986,202
Naples	3,833,805	Goteborg	925,553
Liverpool	2,913,717	Bergen	147,935
Havre	1,738,122	Marseilles	134,496
Manchester	1,278,096	Glasgow	112,259
London	1,120,098		

Very likely some way out of the difficulty will be found before long, but meanwhile the effect on the price of copper will have been felt, and not improbably it will be necessary for the producers to further decrease their output. The cut in production made by the mines is now beginning to show

in the refineries, so that stocks of copper will not increase so fast from now on as they have in the past three months.

The third quarterly report of the Nevada Consolidated Copper Co. contains the following information:

	Third quarter.	Second quarter.
Ore milled, tons	599,126	831,589

The pits at the various mines supplied 96% of the ore, and 4% from underground in the Veteran. The Giroux Consoli-

OPEN-CUT MINING AT ELY, NEVADA.

dated also sent 11,322 tons to the mill. On August 6, on account of the war in Europe, production was reduced to 59% capacity. Copper on hand and in transit at the end of the term amounted to 25,150,319 lb. Undivided profits are $2,786,627.

Antimony was as radically affected by the war as any of the metals. In October, an unusual transaction was the reshipment of metal to Europe, whence most of it had come. A few months ago there was a glut of antimony in the port of New York. Today spot supplies have been practically depleted. Both England and Russia made heavy demands upon American stocks, wanting the metal for the manufacture of bullets, particularly those used in shrapnel. The steamer *Dwinsk*, which sailed from New York, October 15, for Archangel, Russia, carried 172 tons of antimony, and other steamers followed with still larger quantities aboard, the total shipment amounting to several hundred tons. Arrivals of Japanese antimony are expected to relieve the domestic situation. On October 6, quotations were about 13c. for Cookson's, 12c. for Hallett's, and 11c. for other grades. On October 20 prices were about 1c. higher for each grade, and October 27 the quotations were 16 to 17c. for Cookson's, 15 to 16c. for Hallett's and 14 to 15c. for other brands. These prices were for spot metal, futures being obtained at considerably less.

It is reported that the petition of the Minerals Separation, Ltd., for a hearing of its appeal from the San Francisco district court to the Supreme Court of the United States has been granted, and that the trial will proceed. Meanwhile the Minerals Separation has begun a suit against the Miami in the Delaware district, hoping it possible to get a favorable decision there and expecting thereby to bring the suit to the Supreme Court. It is to be hoped that this litigation can be settled soon, as it is causing both the Minerals Separation and the producers to spend a lot of money unproductively, and is delaying the application of flotation to the treatment of copper ores.

The Tonopah Mining Co. is evidently going ahead with the development of its property in Nicaragua, the Edèn Mining Co. having been formed to take it over. At any rate, a charter has been secured for the Tunkey Transportation & Power Co. to build a railroad connecting the property with some other point in Nicaragua which has not yet been fixed. The Company has been incorporated in Delaware, and will be a subsidiary of the Tonopah Mining Company.

There has been a good deal of financial distress in Peru through the temporary closing of the principal banks. The result of this has been that considerable gold coin has been withdrawn from circulation, and the circulation of silver coin has been reduced. At the end of August the government of Peru authorized the national mint to coin any silver that was brought to the mint by individuals, charging a seigniorage of 10%. The government has reserved the right to increase the rate of seigniorage after a period of 30 days.

The Geological Society of America will hold its twenty-seventh annual meeting at Philadelphia, in conjunction with the annual meeting of the American Association for the Advancement of Science, on December 29 to 31. The sessions will be held in the building of the Academy of Natural Sciences. The address of the retiring president, George F. Becker, will deal with 'Isostacy and Radioactivity.' Edmund Otis Hovey is secretary of the Society.

The Montana branch of the American Institute of Mining Engineers met at Butte on October 23. There were 50 engineers present, presided over by E. P. Mathewson, of the Anaconda company. There was lengthy discussion held on the subject of mining claims on the forest reserves. The government's point of view on the question was presented by Chief Forester Silcox, of Missoula. He declared that until recently the government's attitude toward prospectors and miners has been open to much criticism, but that the grounds for this criticism have been removed, and that all possible is being done to encourage prospecting on the reserves.

TORONTO, ONTARIO

THE NICKEL INDUSTRY AND EXPORTS.—IRON MINING INVESTIGATION.

The Sudbury nickel mining industry, which was seriously depressed at the ontset of the war, shows signs of reviving. The International Nickel Co., about 75% of the trade of which was with Germany, has only had two of its six furnaces at Copper Cliff in blast, but has recently started two more. The only one of its mines being worked at the last report was the Creighton, but others may be opened shortly. The only other producing company in the field, the Mond Nickel, all the output of which goes to the British market, has kept busy, and is working five mines, the Victoria, Garson, Kirkwood, Levack, and Worthington. The Mond company is also buying ore for its new smelter at Coniston, from the Alexo nickel mine, near Porcupine. Since the war commenced, attention has been directed to the fact that the Canadian nickel mines have furnished the German government with material for their war vessels, and in fact constitute their only source of supply, and an agitation has been set on foot by the press for prohibiting the export of nickel to foreign countries. As Canada is committed to an active participation in all Imperial wars, it is not at all probable that the present anomalous condition can continue, and government action to compel the refining of all nickel to be done in Canada, and restricting the export of the metal to the British Empire may be expected in the near future.

The Canadian government, which during the last session of parliament gave the iron and steel interests reason to hope that something would be done to encourage iron mining, has appointed a special committee to inquire into the condition of the iron-mining industry. This body comprises four mem-

bers of the staff of the Department of Mines, O. E. Leroy, G. C. Mackenzie, E. Lindeman, and John McLeish, the last named being secretary. The investigation will have a wide scope.

PORCUPINE, ONTARIO

CONDITIONS AT POACUPINE; MEN EMPLOYED, AND WORK AT THE DOME, VIPOND, DOME LAKE, SCHUMACHER, AND HOLLINGER RESERVE MINES.

Production of gold at Porcupine shows a steady increase, largely on account of conditions created by the war. Canadian gold mining companies, under arrangements effected between the Bank of England and the Dominion government, are disposing of their bullion to the bank and delivering it in Ottawa. They are credited with the value at par, and can sell exchange on London to anyone having debts to liquidate in Europe at about 2% above par. The additional premium gives a stimulus to the activity in mining, resulting in a considerably increased output. P. A. Robbins, general manager of the Hollinger, estimates the number of men directly employed around Porcupine at about 2500, and the total number of wage-earners in industries and trades dependent upon mining to be at least as many more. The output during the first half of the present year was over $2,000,000, and the material increase in the production of the leading mines since then indicates that the total production of the year will be over $5,000,000. The Dome has shown the most decided improvement, increasing the monthly tonnage treated to about 22,000, a specially important feature being the reduction of the cost to a trifle less than $2.50 per ton. The grade of ore will soon be decreased to about $3.50, there being about 3,000,000 tons of this grade in sight. At the Vipond, the new Hardinge mill is working well. Ore reserves above the 300-ft. level are estimated to keep the plant going for 20 months. Several new veins have been discovered on the surface.——The new 100-ton stamp-mill of the Dome Lake is in operation. The main shaft is down to 400 ft., where a level is being driven. The ore, assaying between $18 and $25 per ton, is estimated at over 12,000 tons.——The McIntyre company has picked up the contact vein which had faulted on the 500-ft. level, and is endeavoring to cut it at 600 ft.——An arrangement has been effected with the Schumacher to develop the area of McIntyre territory underlying Pearl lake through one of the shafts of that Company.——Hollinger Reserve has gone into liquidation, with liabilities of about $75,000. The mine has ore on the dump valued at about $65,000, but was unable to obtain funds owing to financial conditions.

SILVER CITY, NEW MEXICO

THE MOGOLLON DISTRICT.—PECOS VALLEY OILFIELD.—FIERRO GOLD AND IRON DEVELOPMENT.—BURRO MOUNTAIN EQUIPMENT.—SIERRA COUNTY MINES.—ORGAN AND STEEPLE ROCK DISTRICTS.

Shipments of gold and silver bullion from the large operating companies of Mogollon, Socorro county, to their New York agents were larger during the week ended October 17, than they have been for some time. The Socorro Mining & Milling Co. shipped 24 bars; the Ernestine Mining Co. 21 bars to Eugene Meyer Jr. & Co., and the Deadwood mill 6 bars. There is enough cyanide in the district to last six months. All producing companies are running mines and mills full time, there being no curtailments in any way.——The Precious Metals Exploration Co. is shipping milling ore to the Deadwood mill, and is about to undertake extensive development work in its lower adit.——A cableway has been erected across the Gila river by Thomas Lyons at Gila, and is safely transporting freighters, auto-trucks and all vehicles going and coming on the Mogollon highway. The Gila river is the highest it has been in many years, and operators at Mogollon suffered on account of a lack of means to cross it. They were much gratified at Mr. Lyons' great and much needed improvement. It is reported that one of the Mogollon custom mills is to enlarge its equipment and production.——Assessment work is at a standstill, pending the action of Congress toward the exemption bill, which will not pass unless more interest is shown in the field. There seems to be an equal number in favor of and against the passing of the measure. A similar law was enacted in 1893 and 1894.

The Pecos Valley oil and gas field, in Eddy and Chaves counties, is the scene of considerable drilling, although many have given the field up as hopeless. One company pulled the casing from its 2680-ft. well, and dynamited the hole, removing the rig to Oklahoma. Another has now taken its place and is contemplating the leasing of a large area east of Carlsbad. Drillers were hired in the valley last week. The Carlsbad Oil & Gas Co. is down 2825 ft., and is in oil-bearing sand. Casing is in progress and hopes are high. The district has been quite a disappointment to many, but may yet reveal a deep gusher.

At Fierro, operators of the gold veins discovered in the grano-diorite basin have ceased mining. Several shipments were made to the El Paso smelter, but the veins were not wide enough to be profitably worked. The Colorado Fuel & Iron Co. continues to mine and ship 300 tons of iron ore per day from the Snow Flake cut of the Brockman estate. Phelps, Dodge & Co. has taken out the pumps and stopped all work on its claims at Fierro.

The Burro Mountain Copper Co., at Tyrone, has started 40 men at the site of the proposed 1000-ton mill, who will be engaged all winter in erecting a machine-shop, carpenter shop, ore-crushing house, and sundry other buildings in connection with the mill. Work on the mill proper will not be started until the method of concentration has been fully determined. The experimental mill near the Niagara haulage adit is treating 50 tons of ore per day. The flotation unit installed did not prove satisfactory, and was discarded. A Towne unit was substituted, and from last accounts was giving fairly good results. Regulation of the agitation and oils will doubtless bring the concentrate up to the desired quality. Flotation will be incorporated in the mill to be erected later, and not used as an auxiliary method. Mine waters will solve the wet concentrating problem. The first Carel type Diesel engine installed in the power-plant was successfully started. Another will be tested in a few weeks. The train schedule from Deming to Tyrone is now in operation three days a week, and will not be increased to seven days a week until the camp is producing.

At Steeple Rock, near Duncan, Arizona, George Utter, recent purchaser of the Jim Crow, Carlisle, and other well known gold mines, is unwatering several shafts and doing general road building. A large consignment of mining machinery was received recently. It will probably be several months before shipments will be made.

Sierra county is comparatively active again, and several shipments of silver-lead ore have been made from the Kingston area. The Overlook mine shipped on September 20.——The Bi-Metallic Mining & Milling Co., at Sierra Blanca, has received an air-compressor, drills, and engine. Installation will be made at once. The Company is reported to have opened high-grade ore.——Ore is being opened in the Amethyst mine at Kingston.——There are many promising mines open for lease and bond throughout the district. The Empire Zinc Co. is heavily interested in the Sierra County zinc and lead mines.

The Organ mining district, near Las Cruces, Dona Ana county, is having a revival. The Memphis mine is being worked by two experienced mine operators, and shipments to the El Paso smelter are made now and again. The Stephenson-Bennett property upper level is under lease, and good grade copper-silver ore is being mined.

THE MINING SUMMARY

The news of the week as reported by our special correspondents and reflected by the local press.

ALASKA

A complete report of the preliminary surveys for the railroads in the territory will be submitted to the President of the United States early in 1915, following the conference of Franklin K. Lane, Secretary of the Interior, and William C. Edes and Thomas Riggs, Jr., of the Alaska Engineering Commission, in San Francisco. Mr. Riggs has stated that since June the surveyors ran preliminary lines over 1200 miles of territory, and established definite locations over 100 miles. The Alaska railway bill provides for connecting an open port of the Pacific with the navigable waters of the interior. There are at present three routes under consideration. One extends from Cordova and takes over the Guggenheim road and the Copper River & Northwestern line from Cordova to the Kennecott copper mines; the second route would take over the Alaska Northern for a distance of 71 miles; while the third line, from Valdez, is without construction. The branch lines running from these lines extend into the Matanuska and Bering River coalfields, which were recently reopened to locations under the coal leasing law passed before Congress adjourned. The work has been done in spite of many difficulties. The full commission will meet in Washington on December 1.

Ketchikan

(Special Correspondence.)—The war has put a damper on most of the copper properties in this district, the Rush and Brown mine being the only producer at present.——Some work is planned at McLean's arm on a large porphyry copper deposit, and a drift will be driven into the mountain in hope of cutting secondarily enriched ore. It is also intended to drive for a 24-in. vein of high-grade copper-gold ore at a depth of 400 ft., by putting in a cross-cut 300 ft. from the main drift. ——Gold claims, save those financed by English capital, are being developed at Helm bay, Thorn arm, Hollis, and Dolomi.

Ketchikan, October 23.

Nome

About 2600 people will winter at Nome. The steamer *Victoria*, the last for the season, left on October 30. The gold output of Seward Peninsula is estimated at $3,000,000, or $500,000 over that of last year.

Valdez

As mentioned in the *Press* of October 17, the Valdez Creek Placer Mines Co., of Boston, finished its ditch, pipe-line, and considerable other work. The work was done in a short time, and is a credit to the mining superintendent, Alfred H. Bryant, and to the Joshua Hendy Iron Works, of San Francisco, which supplied the hydraulic plant and two first-class pipe men. The 36-in. pipe will carry 2000 inches of water per 24 hours. There were 54 men employed during the greater part of the season. On September 20, clean-up was started, but on account of freezing weather, only the boxes were cleaned, yielding $4200. From this it is estimated that the pit on bedrock will return over $100,000 next season. The gravel moved in 1913 averaged $2.70 per cubic yard, and allowing for a working season of 150 days, with 6000 yards per day yielding only $1 per yard, the total output next season may be $900,000.

ARIZONA

The first suit filed under the state mine tax law has been reported to the tax commission, the Arizona Copper Co., of Clifton, Greenlee county, appealing against the valuation on its producing mines for 1914. The assessment is about $8,000,000, which the Company wishes reduced to about half. Last year it paid taxes on $9,000,000. The Company wants the Commission to take the cost of recent improvements out of the net, and thereby reduce the valuation for 1914, but the Commission has refused, allowing but 10% on each item, it being estimated that the improvements will last at least 10 years.

Mohave County

The Tom Reed and Gold Road mines continue to produce about $100,000 and $80,000 per month, respectively. The former is opened to 950 ft., and the latter to 900 ft. Large reserves of ore have been developed.

Pinal County

The new 125-ton concentrator of the Kelvin-Sultana Copper Co. started operation on October 26. The mill was designed and built by O. N. Brown. In the mine, three shifts are working, and stoping is in progress on No. 2 vein on the 200-ft. level; while No. 1 west drift on the 500-ft. level has been advanced 82 ft. Preparations are being made to draw ore from the stockpile that has been accumulating for two years.

CALIFORNIA

The committee in charge of organizing an association of California mine operators met at the Crocker building, Thursday, acted on the articles of association, and made arrangements for perfecting the association. It is proposed to call the new organization the California Metal Producers Association. The membership fee will be $25 for concerns employing 25 men or more, and $10 for those employing less. Dues will be based upon the payroll. The association is expected to take an active part in improvement of mining conditions in California. The committee in charge consists of Albert Burch, George W. Starr, G. W. Metcalfe, Newton Cleaveland, J. C. Hutchinson, C. E. Knox, and Seeley W. Mudd.

Amador County

A restraining dam is being constructed by the Central Eureka company on the Allen estate to hold the tailing from its mill. An 8 by 8-in. cement-lined flume, 2500 ft. long, is being built at a cost of $4000. Where this crosses the main Sutter Creek and Jackson road it will be 72 ft. high. A steel head-frame and electric hoist are planned for the mine, which is yielding good returns. J. E. Davis is manager.

Nevada County

At the Golden Center of Grass Valley the new shaft has been sunk 211 ft. in 60 days. Good ore has been opened on No. 5 level.

Shasta County

A suit for $10,000 damages, and an injunction against operating, has been started by George Baker, a farmer owning 2229 acres of land across the river from Redding, against the Mammoth Copper Co. of Kennett, alleging that fume destroyed crops and equipment. The distance between the farm and the smelter is about 12 miles. The injunction suit between the Farmers' Protective Association and the Mammoth Copper Co. has been postponed for three weeks.

Trinity County

(Special Correspondence.)—The Bonanza King company has cut an orebody in No. 4 adit, approximately 200 ft. below the shaft sunk from No. 3 level. The vein is said to be show-

ing good ore, and is probably the main shoot which yielded rich ore in the upper levels. The management has decided to move the mill to the mine, thus avoiding the use of the aerial tramway, constructed several years ago when a 40-stamp mill was constructed. The capacity of the mill has since been reduced to 10 stamps. San Francisco people are interested. ——The Alta Bert Dredging Co. continues to operate with good results near Carrville.——The Trinity Exploration Co. is drilling placer ground along the Trinity river and tributary streams, and has prospected a large area of ground. This work has been in progress nearly a year, and it is understood the management has practically decided to close a deal for the greater part of the land under option.——A. Belli and sons are developing a good body of ore in their property near Coffee. A recent crushing is said to have yielded over $40 per ton.——Considerable prospecting is going on in the Coffee district, mostly on the account of owners.——The Trinity Dredging Co. has installed a new tumbler on its dredge at Lewiston. The boat is the largest operating north of Oroville in California, having 11-cu. ft. buckets. H. L. Cheesebro is superintendent.

Carrville, October 24.

COLORADO

Lake County (Leadville)

The new zinc smelter is shut down temporarily in order to enlarge the bag-house, which will contain 80 more bags.——The Big Five company has constructed a tram from the shaft to the railroad siding, 760 ft. below. This obviates hauling

ZINC OXIDE PLANT AT LEADVILLE. FROM LEFT TO RIGHT: FURNACE SHED, FUME PIPE, BAG-HOUSE, LABORATORY AND OFFICE.

with teams. An electric pump has arrived for the mine.——The Connors lease has shipped 4200 lb. of ore, from which 141 oz. metallics was separated, the remainder assaying 75 oz. gold per ton.——Surface work at the Penrose shaft is progressing well. A 165-hp. motor is to drive the hoist. This property is being prepared for the Down Town pumping scheme.

Summit County

Net earnings of the Tonopah Placers Co., controlled by the Tonopah Mining Co. of Nevada, totaled $145,096 during the quarter ended August 31, 1914.

Teller County (Cripple Creek)

During October the estimated gross value of ore treated in the Cripple Creek district was $1,220,315, from 81,283 tons, an increase of $129,241, and a decrease of 2105 tons. Smelting ore showed an increase of $118,700, the average shipped being $55 per ton. The Golden Cycle output was 28,000 tons, worth $560,000; Portland, 28,050 tons, worth $248,916; Stratton's, 10,828 tons, worth $30,320; Colburn-Ajax, 4305 tons, worth $29,489; while the Wild Horse, Kavanaugh-Jo Dandy, Gaylord-Dante, Isabella, and Free Coinage mills treated from $2 to $4 ore.

An accident to men removing forms from a new concrete magazine at the Cresson mine on October 27, which apparently had not set after five days, resulted in one death and one man badly bruised.——At the Gold King, a man was thrown down an incline shaft, resulting from the breaking of the rope. He is in a serious condition.——The new Sullivan air-compressor at the Vindicator is ready for work.——Three grades of ore are being shipped by Oscar Fogelman from the W. P. H. mine.——An 18-drill Ingersoll-Rand compressor has been purchased for the Blue Bird mine on Bull hill.——There is increased activity in the El Paso property by the Company and lessees.

A suit for $29,000 has been started by J. E. Cooper against the Colorado Gold Mining & Development Co., and others, for breach of contract.

IDAHO

Clearwater County

About $20,000 has been spent by W. J. Harris, of Spokane, in testing 300 acres of gravel on Quartz creek, 30 miles east of Orofino. The 'pay' is from 6 to 14 ft. deep, and pits and drills have proved 4,000,000 cu. yd., containing from 10 to 15c. per yard. An electrically-driven dredge will be constructed at a cost of $75,000, to handle 2500 cu. yd. per day. A company is to be formed with the name of the Quartz Creek Placer Mines. The Pierce district, in which the area is situated, has had a large gold production in the past.

Lemhi County

According to Ralph C. Nichols, a considerable amount of development is being done around Gilmore, and over 100 men are employed at the three producing mines. The Latest Out produced 400 tons of ore assaying 30% lead, 12 to 15 oz. silver, and 75c. gold per ton in October. It also contains an excess of iron. The main shaft is 650 ft. deep on the incline. Water-level is about 700 ft. lower.

Owyhee County

According to J. B. Hamman mineral inspector of the General Land Office at Salt Lake City, Utah, who has recently returned from the South Mountain district, that country is not a good field for prospectors. Spokane people have claims in this district. Mineral deposits in the restricted area are in schist and limestone, around which is a large lava flow that has covered the country.

Shoshone County

The Caledonia, at Wallace, is producing some rich ore. One car recently, from the 300-ft. level, assayed 313 oz. silver, 17% lead, and 7% copper; and one from 500 ft. averaged 486.2 oz. silver, 5.2% lead, and 15.45% copper. The mine is now well developed for mining purposes. It is operated through the Bunker Hill & Sullivan company's Kellogg tunnel. Charles McKinnins is manager.——The Bunker Hill & Sullivan company paid dividend No. 206, of $81,750, on November 4. The total to date is $15,628,500.——A large body of zinc ore has been opened in the Silver Cable, east of Mullan.——The National Copper Co., at Mullan, has suspended work at the mine on account of the metal market.——Adjoining this mine is the Copper King, in which a winze has been sunk 50 ft. in 2 to 2.5% copper and 20 to 30-oz. silver ore.——The Idaho Gulch district, near Murray, is proving a promising area, although it is difficult of access. At the Silver Dollar several adits have been driven and a vein of quartz, galena, and iron is being opened.

The decision of the District Court of Idaho, in the suit of the Bunker Hill & Sullivan company of Idaho, against the Stewart Mining Co., has been upheld by the U. S. Circuit Court of Appeals at San Francisco on November 2. Jonathan Bourne owns the patented mining claim Ontario, which has been worked for some years by the Bunker Hill company. The Stewart company owns the Senator Stewart Fraction, a claim

which adjoins the Ontario. Suits were first brought in the state courts by the Bunker Hill to prevent the Stewart people from working underneath the Bourne claim. The Stewart company set up the plea that its ore extended underneath the Bourne claim and claimed ownership on the theory of extralateral rights. The state courts decided in favor of Bourne. In the opinion of the circuit judges the apex alleged by the appellants does not exist.

ILLINOIS

St. Clair County

The Granby Mining & Smelting Co. announces that it will begin operating the Rose Lake plant January 1 and will employ about 1000 men.

MICHIGAN

Houghton County

The Isle Royale mine is producing 2100 tons of 'rock' per day, or 300 tons above the period before the strike in 1913, and with about the same number of miners. The output of copper in September was 605,280 lb., at a cost of under 11c. per pound.——There are 340 men at the Mass, and the daily output is 1000 tons, but if copper remains at its present price, there must be either a reduction in wages or the property close.——The Superior is working at normal pace, or 700 tons per day.

MISSOURI

Phelps County

The School of Mines and Metallurgy of the University of Missouri, at Rolla, has issued its forty-third catalogue. It contains details of the faculty, history of the school, finances, buildings (which are shown), regulations for admission, and courses. The institution is in Phelps county, comparatively near the lead district of Flat river, zinc district of Joplin, and the smelter, coal-mining, clay-working, and cement industries of the state.

NEVADA

Churchill County

The Nevada Wonder Mining Co. declared a dividend of 5% on October 28, payable November 21 to stockholders of record October 31. Books close October 31 and open November 8. This is the fourth semi-annual dividend paid by the Company, the other three being 10c. per share. J. A. Burgess is superintendent.——The Nevada Hills produced 5317 tons of $7.16 ore in September, with a profit of $4597. Resources on September 30 totaled $246,748, including silver worth $12,467, about 24,000 ounces.

Clark County

Platinum was recently found in the Boss mine in the Yellow Pine district; now it has been identified in the Aura Amigo claim, one mile north. The Boss ore occurs in limestone and is quite flat. It is reported that the Boss mine has been sold to Seeley W. Mudd and others, of Los Angeles, for $250,000, of which $50,000 has been paid.

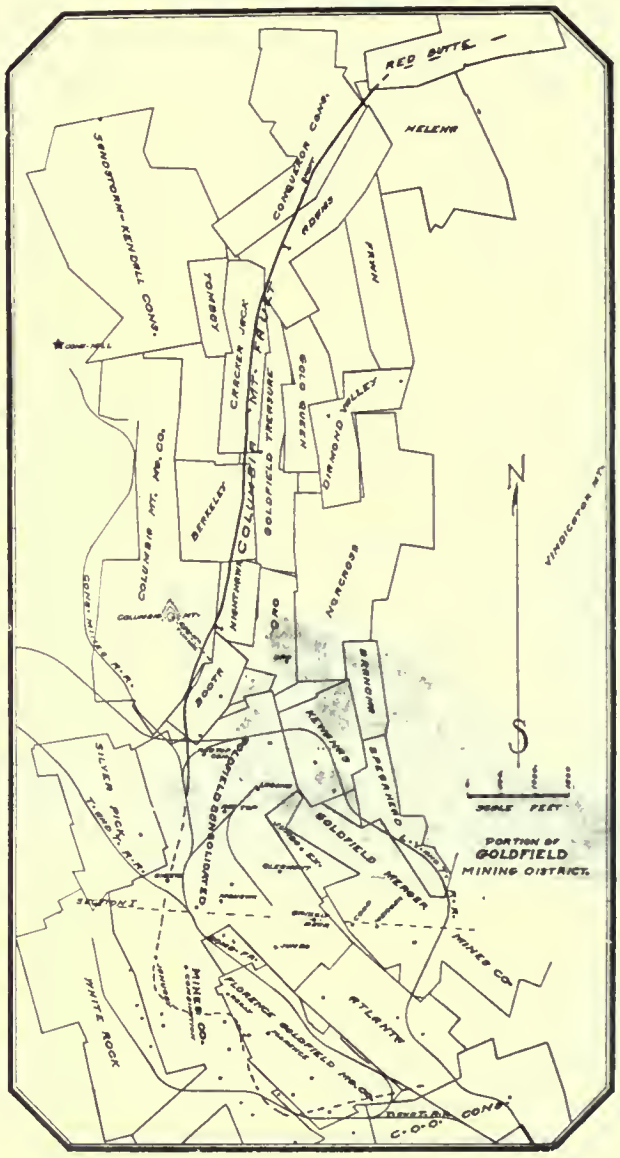
Elko County

Since June, the Dome Mining & Reduction Co., at Bullion, has sent 1700 tons of lead-silver-copper ore, and lessees 500 tons additional, to Salt Lake smelters. Auto-trucks haul the ore to the Eureka and Palisade railway. Ralph M. Kellogg is superintendent of the property, which is 30 miles south of Elko.

Esmeralda County

The Jumbo Extension company has declared a dividend of 5c. per share, equal to $62,500, making a total of $159,616 to date. The last distribution was made in July 1911, when the Vinagarone Fraction claim was sold to the Goldfield Consolidated. The present amount is from ore recently extracted. During September, 776 tons was sent to the Consolidated mill, assaying $15.51 per ton, and 930 tons of $56.30 ore was sold to the Western Ore Purchasing Co. The net profit on all ore was $35,153. Development totaled 532 ft. at $6.28 per foot. Mining cost $2.75, and all costs totaled $4.46 per ton. Ore blocked out on two or more sides is valued at $400,000. Cash and ore in transit on October 31 totaled about $100,500. October profits are estimated at $75,000.

The Goldfield Merger Mines Co., with A. I. D'Arcy in charge, has issued a report covering the term October 1911 to October 1914. When starting in the former year, it was decided to sink a large 3-compartment shaft. A complete surface and



mine equipment was installed. At 650 ft., the St. Ives shaft met with water, so pumps were started. In August 1912 the shaft was 1325 ft. deep, and 1475 ft. of work was done in a latite-shale contact, and connection made with the Grizzly Bear claim of the Goldfield Consolidated. No commercial ore was proved. In June 1913 the shaft was down 1772 ft., and at 1725 ft. a cross-cut was driven to the Atlanta property. The Atlanta Mines Co. advanced $35,000 toward sinking the shaft under certain conditions, of mutual benefit. The Atlanta extended the Merger cross-cut at 1725 ft. into its own ground, with encouraging results. A heavy flow of water stopped further work, and new pumps should be ready for work in a few days. When the water is drained, the Atlanta will open the vein found, by driving toward the contact. This development promises well for the Merger company. To develop the latter's Velvet claim, an agreement was made in

December 1912 with the Jumbo Extension company to use its shaft. A low-grade ore-shoot was opened. The Extension offered to buy the claim, and a deal was made for $85,000 and 150,000 shares. At present a drift is being driven in the contact from No. 7 level of the Grizzly Bear claim of the Consolidated. The work being done by the Atlanta company will help considerably the future of the Merger mine.

The Goldfield Consolidated company's estimated output in October was as follows: Ore treated, 28,660 tons; recovery, $334,000; and net realization, $149,000.

Lyon County

Thirty-two men are working on the site for the Nevada-Douglas leaching plant. All material has been ordered, and it is hoped to start treatment early in 1915. The plant is designed to treat 50 tons of sulphide ore in 24 hours, and the acid derived from this ore will be enough to treat about 200 tons of oxidized ore per day, so that the daily capacity will be about 250 tons.

Nye County

At Manhattan, work in the Mushett-Wittenberg 10-stamp mill on White Caps oxidized ore is better than expected. Ore worth $10 per ton gives a residue of 40 to 60c. Mining costs $1 per ton, and will be reduced. Reserves of oxidized ore are 4000 tons assaying $10 per ton.——Grading for the new Mushett-Wittenberg mill at the Big Pine is under way, and the machinery should soon be on the ground. The daily capacity is to be 200 tons.——Sub-lessees in the Manhattan Dexter are opening rich ore at 325 ft. The Union shaft supplies water for the Mushett-Wittenberg mill.

The output of eight mines at Tonopah last week totaled 10,835 tons, worth $210,990.——Tonopah has had another fire, and two blocks of residences, worth $20,000, were destroyed, on October 30. The West End mine plant was in the area, and houses were dynamited and the shaft closed.

Seventeen different stopes in the Belmont mine are supplying ore for the mill.——During the quarter ended August 31, 1914, the Tonopah Mining Co. produced bullion worth $552,116. Net earnings were $218,783. A dividend of $250,000 was paid on July 31, and another on October 21. Including cash $293,310, the surplus on August 31 was $1,680,194.——An electric haulage plant has been arranged at 950 ft. in the Extension, between the incline and vertical shafts. A Nordberg double-drum electric hoist has been ordered for the new shaft. Sinking from the 1170-ft. level is to be started soon. Sixteen stopes are supplying ore for the mill.——Development in the Montana last week totaled 165 ft.——No. 1 shaft of the Buckeye-Belmont is nearly retimbered. The vein at 1200 ft. is then to be opened.——Work at Tonogold is still quite encouraging.

White Pine County

A large blast was set off at the Liberty pit of the Nevada Consolidated on October 26. Twelve holes, from 65 to 125 ft. deep, were drilled, and loaded with 58,050 lb., or 29 tons, of powder. It is estimated that 200,000 cu. yd. of ground was moved. It dropped about 30 ft. in all.

NEW MEXICO

The value of the mineral products of New Mexico, according to the U. S. Geological Survey, increaaed from $14,391,355 in 1912 to $17,862,369 in 1913. The figures for 1913 are more than double those of two years ago, the increase being due principally to activity in the production of copper.

The New Mexico School of Mines, at Socorro, has opened with a registration 20% higher than that of last year, and numbers 50 students in all. This is in spite of the fact that the Texas School of Mines and Metallurgy has been opened at El Paso, a short distance south. The faculty has also been enlarged. The school is making a most creditable showing and is closely allied with the mining industry.

OREGON

Baker County

Installation of plant at the Cornucopia Mines Co.'s Last Chance mine, which is leased to the Baker Gold Mines Co., is finished.——The Flagstaff mine is being reopened by J. G. Cleary and associates of Boston.——The Eastern Oregon Light & Power Co. is suing the Highland Gold Mines Co. for $4185, for power and machinery supplied.——Liens for labor and supplies, amounting to over $1500, have been filed against the Mammoth Mining Co., near Baker.——A new 10-stamp mill is under construction at the Golden Gate mine, in the Greenhorn district.

UTAH

Emery County

With Theodore Garvin in charge, the Duchene Assessment Association of Pennsylvania is drilling for oil at Temple Wash in the San Rafael desert. Holes are drilled to about 600 ft. Water has been encountered in large quantities between 500 and 600 ft. Coal costs $25 per ton in this district. Several crews, 8 to 10 men in each, are employed.

Juab County

East Tintic properties are to be consolidated by the Tintic Coalition Mines Co., which absorbs the East Tintic Development Co., Provo Mining Co., Eureka Lilly Mining Co., Little Silver King claim, Little Silver King Sideline extension, and eight other fractional claims containing about 100 acres. The Company is capitalized at $500,000, with shares of a par value of 50c. each. Of the 1,000,000 shares, 400,000 will be issued, and 600,000 placed in the treasury for development purposes. S. S. Arntz is president, H. G. Snyder vice-president and treasurer, J. E. Galigher secretary, and J. B. Jenson and Henry I. Moore, additional directors. The properties have some equipment, and have produced lead and zinc ores.——The Iron Blossom and other Knight mines will continue to produce lead-silver ore in spite of the low prices of these metals, and the higher-grade ore will be shipped, according to Frank Birch, assistant manager of the properties.

Salt Lake County

Messrs. Grove, McCormick, and Lark have been appointed trustees for the Ohio Copper Co. No move will be made to resume mining and milling until copper is higher.——At the Cardiff, in the south fork of Big Cottonwood, the vein has been opened for 65 ft., and now shows 9 ft. of ore. It was cut in the adit at 2600 ft., in a contact of quartzite and lime. A shipment is to be made to the smelter at Murray.

Utah County

About 100,000 tons of zinc ore has been opened in an adit of the Santaquin King mine, 80 miles south of Salt Lake City, yet the main orebody has not been reached. This development is expected at any time.

WASHINGTON

Ferry County

Republic is showing considerable activity, and there are few empty houses in the town.——The Ben Hur Leasing Co. has sunk its shaft to 700 ft., and is employing 30 men in ore-breaking.——The Western Union Mines is also getting started at the mines it has recently acquired.

CANADA

British Columbia

At Windfall cañon, the Exploration Syndicate of New York has suspended work for the season. Under the supervision of T. W. Beam, of Denver, over 6000 ft. of diamond drilling was done, holes varying from 700 to 1800 ft. deep.—At the Jewel mine, near Greenwood, the 500-ft. level is being opened. The mill is yielding good returns. C. A. Banks is in charge.

——Construction of surface plant at the Surf Inlet mine of the Tonopah Belmont company of Nevada has been finished and development has been commenced on ore in the old lower adit. A cross-cut is being driven to cut the vein below the adit.

ONTARIO

Eight claims for damages for injuries against various mining companies in the north are being heard in the courts.—— At Cobalt, La Rose company proposes to sink a new shaft in unprospected ground on La Rose Extension, remove overburden on the east of the main La Rose claim, and look for surface veins, discontinue work in the Princess claim when the present ore is extracted, cross-cut in the south part of the Lawson claim under the diabase, and close down the Fisher Eplett claim. The Company paid its regular quarterly dividend of 2½% last week, amounting to $187,000. This was from accumulated profits. The surplus on October 1 was $1,396,620.——The annual meeting of the Temiskaming & Hudson Bay Mining Co. was held on October 25. Work was stopped at No. 1 mine in June, as the ore was all extracted. Prospects in No. 2 are encouraging. Silver production was 393,360 oz., worth $196,436, and a total to date of 5,604,168 oz., with a net value of $2,965,423. The profit for the year was $52,561. Four 300% dividends were paid. The Company has entered the Porcupine field and holds 540,000 out of 940,312 shares in the Dome Lake Mining & Milling Co. The Temiskaming mill was stopped on August 1, but it is to be restarted in the near future. At 750 ft. in the mine there is showing 4 to 6 in. of 2500-oz. ore.——Work in the bottom of Kerr lake is opening good ore. All of the mud will not be out this year.——A station has been cut at 900 ft. in the Beaver, and sinking is to be continued to 1000 feet.

At Porcupine, the Hollinger has paid its regular monthly dividend of $90,000, making 81% since 1912, equal to $2,430,000, on a capital of 600,000 shares of $5 each par value.—— F. W. Schumacher, of Columbus, Ohio, owner of the Schumacher property, is having plans drawn for a 100-ton mill. ——The McIntyre mill is treating 275 tons of $9.50 ore per day. Underground work is quite satisfactory.——At the Jupiter, under option to the McKinley-Darragh-Savage company, the 400 and 475-ft. levels are being developed by 40 men and four drills. Good ore is opened at both depths.

YUKON

The Canadian Klondyke dredges recovered 1646, 2273, and 1967 oz. gold respectively during the weeks ended October 3, 10, and 17.

COLOMBIA

The Pato dredge treated 77,600 cu. yd., yielding gold worth $10,850, during the week ended October 13. The London office stated that probably a large part of this material was old tailing which had to be dug through in moving the boat to its new position.

MEXICO

NUEVO LEON

Operations of the American Smelting & Refining Co., Fundicion de Fierro y de Acero de Monterey, and the Monterey Tramways Co., at Monterey, are considerably interfered with by strikes. No compromise is in sight.——There are about 700 smelter laborers who demand an 8-hour day and more pay with Sunday off, instead of the 12-hour shifts they are working. The steel works and tramways have the same trouble.

TAMAULIPAS

Oil exports from Tampico, from October 15 to 20 inclusive, totaled 449,618 bbl. on 16 steamers and barges. During the second 10 days of the month the exports were 76,140 bbl. more than in the same period of September.

PERSONAL

FRED SEARLES is in Mexico.

G. W. STARR was in town Wednesday.

W. H. KNOWLES is down from Sonora.

G. W. METCALFE was in San Francisco.

J. PARKE CHANNING has returned to New York.

CHARLES S. SPRAGUE has returned to Goldfield after a vacation spent in San Francisco.

E. H. CLARK, president of the Homestake Mining Co., was recently at Lead, and has gone back to New York.

J. F. CALLBREATH is at Battle Creek, Michigan, where he has gone to recuperate after a severe nervous breakdown.

J. W. HUTCHINSON, of the Goldfield Consolidated, left the Adler Sanatorium, San Francisco, recently for Colorado.

RALPH C. NICHOLS, of Gilmore, Idaho, has been at Salt Lake City to arrange contracts for ore from the Latest Out mine.

MORTON WEBBER was recently engaged in examination work in the southeast Missouri lead belt on behalf of Eastern interests.

FREDERICK BRADSHAW has returned to Tonopah, Nevada, from a visit to the Belmont company's mine at Surf Inlet, British Columbia.

W. F. NEWMAN sailed from New York on the *Adriatic*, on his way to London from Peking, where he has been representing British Manufacturers, Ltd.

H. A. J. WILKENS, president, and W. B. DEVEREUX, JR., general manager, of the Mines Management Co., are now in California examining properties in the state with a view to commencing operations.

Following is the personnel of the management of the Tom Reed Gold Mines Co.: CHARLES GRIMES, president and treasurer; CHARLES MUSHRUSH, vice-president; W. J. LAWRENCE, secretary; S. S. JONES, general manager; B. L. LUNCEFORD, assistant manager and superintendent of mill; S. R. REEVES, assistant superintendent and auditor; WILLIAM H. FLANNIGAN, mine superintendent; J. D. SPERR, mining engineer; and J. S. WITHERS, bookkeeper.

Obituary

CHARLES J. BANDMANN, mining engineer and son of the late Julius Bandmann, died on November 1 of heart failure. Mr. Bandmann was about 50 years of age and was a resident of California. His death will be regretted by his many friends.

ANTON J. JACOBSON, familiarly and pleasantly known to his friends as 'Tony,' died at Salt Lake City, October 29. He was prominent in Utah mining, having operated in Pioche, Stockton, Deer Lodge, Stillwater, and other districts and was especially well known for his work in reviving activity at Alta.

DAVID JOHN KELLY, who died at Salt Lake City, October 10, at the age of 37, was a native of Utah, educated in the Salt Lake City schools, receiving the degree of M.E. from the University of Utah. In 1898-9 he was working under George Moore, as assayer, for the Salt Lake branch of the Consolidated Kansas City Smelting & Refining Co. In 1901 he was again with George Moore at Sunshine, Utah, where the Moore filter was born, and at which time he conceived the idea of the Kelly filter press. It was not until 1905, however, that he built his first working model and demonstrated the soundness of his theory. With faith, courage, and perseverance, through financial vicissitudes, mechanical and other difficulties, he struggled on, until the Kelly filter press achieved its present position in the metallurgical and manufacturing world. He was a man of winning personality and leaves many devoted friends, as well as a widow and two young sons.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, November 5.

Antimony	15 —15¾
Electrolytic copper	13 —13¼
Pig lead	3.75— 4.70
Quicksilver (flask)	$55
Tin	36 —37½
Spelter	6½— 6¾
Zinc dust, 100-kg. zinc-lined cases	10

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, November 5.—The situation today is as follows: copper is slightly higher than the 11.20c. price of a few days ago, there being more domestic inquiries; lead is firmer at 3.50c.; and spelter is quiet at 4.90c. per pound.

The board of managers of the New York Metal Exchange, at a meeting held October 30, passed the following resolutions: "Whereas, the London Metal Exchange will open for business November 9, be it resolved, that the New York Metal Exchange be opened November 9 for trading in tin, in accordance with the recommendations of the pig tin committee. Call will be held at noon."

On the following page will be found a discussion of the metal markets in October. Copper and antimony are also discussed in the New York letter of this issue.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

The falling tendency has been arrested somewhat, the lowest recorded being 48⅛c. New York, and 22.19d. London. On November 5 these prices improved to 49⅛c. and 22 7/0d. respectively. At Salt Lake City, the U. S. Assay Office is now paying only 18c. for silver contained in gold received. The government of Peru is receiving silver for coinage at the mint at Lima under certain conditions. Imports of metal into England to the end of September totaled 72,600,000 oz., compared with 89,600,000 and 98,300,000 oz. respectively during that period of 1913 and 1912. Samuel Montagu & Co. states that one important factor connected with the recent increase of supplies was the fall in value of the Mexican 'peso,' which operated as a bounty to the mining interests of that country. This firm cannot regard the immediate future of silver with optimism. Inquiry from the Far East, or large coinage orders would affect prices. Pixley and Abell's circular shows that to October 15, exports of silver from London to the East were £4,625,500, against £8,847,000 in the same period of 1913, equal to a decrease of about 40,000,000 ounces.

COPPER

Prices of electrolytic in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	16.51	14.21	July	14.21	13.26
Feb.	14.93	14.46	Aug.	15.42	12.31
Mch.	14.72	14.11	Sept.	16.23	12.02
Apr.	15.22	14.19	Oct.	16.31	....
May	15.42	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

The copper situation is discussed elsewhere in this issue. Prices have been from 11.15 to 11.30c. per pound. No average for October is possible so far. The Granby company's Anyox, B. C., smelter produced 1,800,000 lb. in October; Kyshtim, Russia, 1,212,400 lb. in period ended October 10; and Braden, Chile, 3,130,000 lb. in September from 81,777 tons of 2.06% ore, with 76.91% recovery.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Oct. 29	3.50	Sept. 16	3.85
" 30	3.50	" 23	3.85
" 31	3.50	" 30	3.75
Nov. 1 Sunday		Oct. 14	3.75
" 2	3.50	" 21	3.50
" 3	3.50	" 28	3.50
" 4	3.50	Nov. 4	3.50

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	4.28	4.11	July	4.35	3.80
Feb.	4.33	4.02	Aug.	4.60	3.86
Mch.	4.32	3.94	Sept.	4.70	3.82
Apr.	4.36	3.86	Oct.	4.37	3.60
May	4.34	3.90	Nov.	4.16	....
June	4.33	3.90	Dec.	4.02	....

Lead is firm at St. Louis at 3.35 to 3.37½c. per pound. At Joplin, Missouri, lead ore is unchanged at $40 per ton.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Oct. 8	55.00	Oct. 22	50.00
" 15	55.00	" 29	50.00
		Nov. 5	55.00

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	39.37	39.25	July	41.00	37.50
Feb.	41.00	39.00	Aug.	40.50	80.00
Mch.	40.20	39.00	Sept.	39.70	76.25
Apr.	41.00	38.90	Oct.	39.37	53.00
May	40.25	39.00	Nov.	39.40	....
June	41.00	38.60	Dec.	40.00	....

Quicksilver is stronger, and a cable from London to local dealers states that there has been an advance from the average of £7 per flask in September, and the rise to £9 early in October, to £11 on November 4, showing that the British government is controlling supplies, which are apparently low.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Date.		Average week ending	
Oct. 29	4.90	Sept. 16	5.25
" 30	4.90	" 23	5.00
" 31	4.90	" 30	4.88
Nov. 1 Sunday		Oct. 14	4.75
" 2	4.90	" 21	4.73
" 3	4.90	" 28	4.90
" 4	4.90	Nov. 4	4.90

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	6.88	5.14	July	5.11	4.75
Feb.	6.13	5.22	Aug.	5.51	5.45
Mch.	5.94	5.12	Sept.	5.55	5.16
Apr.	5.52	4.98	Oct.	5.22	4.75
May	5.23	4.91	Nov.	5.09	....
June	5.00	4.84	Dec.	5.07	....

Spelter is dull at St. Louis at 4.90c. per pound. At Joplin, Missouri, there has been an advance of $5 per ton for ore of 60% metal content, prices being $42 to $46 per ton.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	50.45	37.85	July	40.70	31.60
Feb.	49.07	39.76	Aug.	41.75	30.20
Mch.	46.95	38.10	Sept.	42.45	30.10
Apr.	49.00	36.10	Oct.	40.61	30.40
May	49.10	33.29	Nov.	39.77	....
June	45.10	30.72	Dec.	37.57	....

The average in October was 30.40c. per pound. The market at present is somewhat sensitive. Futures are neglected, although there are sellers for December and January at 30½c. Supplies due are small.

New York Metal Review

The European war affected the metal market considerably in October. Copper, the price of which went as low as 11.12½c., was seized en route to Mediterranean ports by the British authorities in their campaign to keep the metal out of the hands of the Germans. After several vessels had been held up, the leading American producers lodged a formal protest with the United States government. A pleasing feature was a buying movement, in which domestic consumers took hold. The price of lead was reduced twice in the month, which, with a curtailment in production, started buying. Spelter again was sustained by heavy exports, especially to Russia. Tin quotations, which touched the lowest level in years, started upward on receipt of the news that the German man-o'-war *Emden* had sunk an English vessel carrying 850 tons of the metal; then declined again. Antimony has been exported heavily, Russia taking large quantities for war purposes, and its price is high as a result of the depletion of spot stocks. In aluminum, little or no interest has been shown. The action of the Secretary of the Treasury in ordering customs collectors to withhold for 30 days all statistics as to exports will greatly retard the completion of metal export figures.

COPPER

The last part of October brought some developments of a most unusual character to the copper market. As mentioned in the last review, England had not only placed the metal on its list of conditional contraband, but had seized stocks stored in Holland, and also some vessels bound for that country with copper among their cargoes. Later, ships bound for Mediterranean ports were held up for the same reason. A formal protest was telegraphed to Washington on October 28 by the leading copper-selling agencies, namely, the American Smelting & Refining Co., American Metal Co., Ltd., United Metals Selling Co., and Consolidated Metals Co. These firms represent nearly 90% of the copper export trade of the United States. Following the sending of the protest, an intimation came from Washington that England probably would release the vessels, in view of Italy having placed an embargo on the exportation of copper from that country, and would guard against its reshipment to Germany. The last named country is known to be short of copper.

A second feature of the month was a comparatively good buying movement, in which action was taken by both foreign and domestic consumers. The net loss in quotations between the first and the end of the month was about ½c., the price for electrolytic on October 1 being 11.75c., cash, New York, while on October 30 it was 11.25c. At the end of the first week, 11.50c. was the quotation; 11.25c. was reached October 19. Three days later the quotation dropped to 11.12½c., cash, but it stayed there only a couple of days, then returned to 11.25c. In the first half of the month the buying was light, and the market in every way monotonous. With the beginning of the last half of the month, some buying was reported, on the part of France in particular, but the aggregate was only fair at best. About October 23, both American and foreign consumers took hold in a lively way, and the total of orders booked was the largest of many weeks. Not a little of the metal sold for export was intended for Germany, shipment to be made through neutral countries. It was understood that the shippers were proceeding on the basis that if Germany received the metal she would pay a large premium, while if England seized it she would, according to her promise, pay for it. Some dissatisfaction was heard, however, as to the basis on which England was willing to settle. The exports of the month up to the 30th totaled 23,414 tons. Lake copper was in some demand from the ammunition makers, who were willing to pay fancy prices for high grades. Quotations for Lake dropped from 12c. to 11.50c. The Waterbury average for September was 12.87½c. Hot rolled sheet copper was reduced ½c., October 1, to 17c. base, and again ½c., October 22, to 16½c. base.

LEAD

The chief features of the lead market in October were two reductions in price and extreme dullness, followed by a good buying movement. The first reduction was made on October 5, when the American Smelting & Refining Co. reduced its New York price from 3.70 to 3.60c. per pound, and the second on October 7, when there was a cut to 3.50c. Both reductions resulted from the zeal with which independent producers went after business. The St. Louis price dropped to 3.35c. Shortly after the middle of October, the announcement was made that some leading producers in Missouri and elsewhere had curtailed their output about 25%, and this, together with the realization that the metal was extremely cheap, caused consumers to enter the market, and in some cases to buy more heavily than their actual needs warranted. October 30, quotations stood at 3.50c. New York, and 3.35c. St. Louis.

SPELTER

In October large quantities of spelter were again shipped to Europe, especially Russia. The month opened with the market on the decline, the heavy exports of September, estimated at 17,000 tons, having subsided, while domestic conditions were dull. The New York price, October 2, was 5c.; October 9, 4.85c.; and October 16, 4.75c. Then came new inquiries from abroad, with some from domestic sources also. These, coupled with reports that there had been a curtailment of production, caused the market to take an upward turn. The quotation October 23 was 5.10 to 5.15c., and on October 30, 5.05 to 5.10c. The last export movement involved a good tonnage, the quantity exported, October 1 to 30, being 6175 tons, making a total of over 23,000 tons since the war started. The steamer *Czar* for Archangel, Russia, from New York, carried 300 tons.

TIN

Just after the war started, as will be remembered, the price of tin soared to 68c. per lb., yet on October 15 the price was down to 28.40c., the lowest in many years. A dull market and ample supply was the cause of the slump. In London, early in the month, trading in prompt shipments and deliveries to be made within 14 days was allowed on the metal exchange there, and this caused such deliveries to decline, as it had the effect of forcing settlements on commitments falling due. It also was announced that trading in all positions would be resumed early in November on the London Metal Exchange, which caused uneasiness both in London and New York. Imports became a little lighter toward the latter part of October, which strengthened the market and caused sellers to hold off in quoting for a time, as they anticipated higher prices. October 21, considerable excitement was caused by the news that the German cruiser *Emden* had sunk the steamer *Trolius*, shortly after the latter ship had left Singapore with 850 tons of tin aboard. On that day, the market advanced from 29 to 30.50c. A good business was done, and more could have been done had not sellers withdrawn from the market, some of them, in fact, becoming buyers. The market on October 22 was active, about 300 tons being traded in. The course of prices in the month is indicated by the following: October 1, 31.05c.; October 6, 30.87½c.; October 13, 29.75c.; October 15, 28.40c.; October 20, 29c.; October 22, 31.50c.; October 27, 30.75c.; and October 30, 30.25c. In Holland, on September 30, there was stored 4437 tons of Banca tin, as compared with 173 tons on the same date in 1913. Domestic deliveries in September are estimated at 2800 tons, which would leave stocks at about 1000 tons. October 30, there was afloat 2145 tons, and arrivals to that date totaled 2043 tons. At Rotterdam, November 10, 850 tons of Banca tin will be sold at public auction.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.
6s-12 oz.-40s	8¾	6s-14 oz.-20s	9½
6s-12 oz.-20s	9	6s-16 oz.-40s	10
6s-14 oz.-40s	9¼	6s-16 oz.-20s	10¼

Extra hard 1c. per set higher than the above.

The following prices are for oils (Calol) in wood barrels; cases (2-5 gal.) 3c. per gallon higher.

	Per gal., cents.		Per gal., cents.
Compressor oil	40	Light gas engine oil	28
Amber gas engine oil	40	Red compressor oil	26
Castor machine oil	20	Red engine oil	17
Dynamo and motor oil	24	Turbine oil	35
Engine oil	24	Turbine oil, heavy	35
Gas engine oil	26	Diesel engine oil	40
Heavy gas engine oil	45	Cylinder oil	37
Heavy red engine oil	19	High-pressure cylinder oil	50
Heavy red journal oil	21	Low-pressure cylinder oil	37
Ice machine oil	28	Valve oil	50

The following prices are for oils in iron barrels, cases (2-5 gal.) 7c. per gallon higher, except on Eocene, which is 8c. per gallon higher.

	Per gal., cents.		Per gal., cents.
Pearl oil	9	Engine distillate	7
Headlight oil	10	Aroturps	23
Eocene oil	11	V. M. and P. naptha	11½
Red Crown gasoline	13½		

	Per bbl
Star fuel oil, f.o.b. Richmond Refinery	$0 85

	Per ton.
Petrolastic cement X	$13.00
Petrolastic cement XX	12.00
Asphaltum	$5.50 to 12.50

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked *.

	Min.	Max.

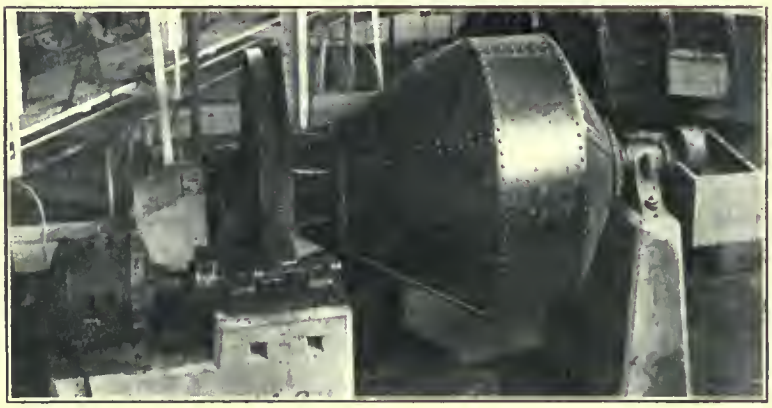
*Extra charge for packing nitric acid for shipment to conform to regulations.

Manganese ore to be used on the Pacific Coast, according to Atkins, Kroll & Co., of San Francisco, would have to contain 90 to 95% MnO_2, and not more than ¾ of 1% of iron. The principal market for this ore is at Atlantic Coast ports.

New Machines and Devices

Motors for Driving Hardinge Mills

When the Hardinge mill regrinding plant of the Calumet & Hecla Mining Co., at Lake Linden, was constructed it was decided to use 75-hp. squirrel-cage motors, equipped with starting-boxes, for driving the mills. Tests on the duty of the motors showed that they actually required about 52 hp. during regular running, the extra capacity of the motors only being required in starting. When the use of 8-ft. Hardinge mills was decided upon for the Baltic mill of the Copper Range Consolidated Mining Co., the management desired to find some more economical arrangement than the use of 75-hp. motors for the handling of 52-hp. loads, and secured the coöperation of the Westinghouse Electric & Manufacturing Co., which offered to develop a special high-efficiency 50-hp. motor built on new all steel frames, which would be capable of carrying these mills successfully, and which would have sufficient torque to start the mill if the motor were thrown directly on the line without the use of a starting-box. This made such a large saving that despite the special features of the motor, it could be furnished at a very much less figure than the standard 75-hp. motor with a starting-box, and the same equipment was ordered for the Champion mill. The point of particular interest about these motors is the rugged frame construction. The frame itself, instead of being of cast iron, is of a rolled open-hearth steel billet forged into a circle by means of a special up-setting machine and butt welded. To these are bolted steel end-brackets. The motor feet are of heavy pressed steel, stamped with a special die and welded to the motor frame. This gives an extremely rugged construction. In fact, the frames on these 50-hp. motors are stronger mechanically than the cast iron frames on the ordinary 75-hp. motors. The construction used makes the motor particularly suitable for strains of the heavy starting duty and for the vibrations incident to direct-connected gear drive.



MOTOR DRIVE FOR HARDINGE MILL.

Since the motors have been installed they have been remarkably successful, and the Westinghouse company has advocated the same type of motor for numerous other Hardinge mill installations. The entire efficiency is very good, and, due to the motors being well loaded, their power factor is high. The cost of the installation is said to have been 70% of what it would have been with 75-hp. motors and starting-boxes.

Commercial Paragraphs

Mark Manufacturing Co., Evanston, Illinois, is distributing a folder announcement regarding the cold drawn steel union. Many advantages are claimed for this type of union.

W. S. Rockwell Co., New York City, has for distribution a heavy cardboard hanger containing a comparative Fahrenheit and Centigrade scale, temperature conversion factors, hardening heats, and tempering heats.

The Pitometer Co., New York City. A folder descriptive of the Cole pitometer, which is claimed accurately records the flow of water through pipes. Its pen draws an ink record on a chart with ordinates directly proportional to the flow.

The 'October Reminder' of the Robins Conveying Belt Co., New York, contains a short description, with illustrations, of a recent unloading, storing, and reclaiming system constructed by this Company.

E. Leitz, New York City. Catalogue No. 43-B, devoted to petrological and metallographic microscopes. Catalogue is fully illustrated and contains prices of various instruments manufactured.

Goodsell Packing Co., Chicago, Illinois, is distributing an announcement regarding the packing specialties manufactured by this Company. The list contains 14 products for a wide variety of purposes.

Havana Manufacturing Co., Havana, Illinois. The 'Havana' double grip friction clutch pulley for gas, gasoline, and oil engines embodies several interesting features which are described in a bulletin on this subject.

E. H. Moyle Engineering & Equipment Co., Los Angeles. An announcement regarding the prospectors' portable rapid-drop mill. The stamp involves many novel features, and is particularly adapted to the use of the small operator.

The United Metal Hose Co., of 510-512 West 24th St., New York City, is offering to send engineers a length of its 'dreadnaught' hose, complete with fittings, on a trial basis. If the hose is not satisfactory, it may be returned at the expense of the Company.

National Tube Co., Pittsburgh. Bulletin No. 7-D, devoted to N. T. C. regrinding valves. The regrinding is one of the conspicuous features; the ease and speed with which this work can be done is most commendable. On a test machine under pressure of 125 lb., one of these valves was opened and closed 3,046,280 times.

The Link-Belt Co., Chicago, Illinois, has recently published a new edition of 'Steel Chains' or Book Number 124. This book is of interest and value to the user of chains, containing a large amount of data on chain construction and use. Sprocket wheels are also included in the catalogue. The Company is also distributing a folder descriptive of the 'Type K' link-belt loader.

McConroy Co., Inc., Philadelphia, Pennsylvania, has recently taken over the all-metal hose business of the Schoen-Jackson company of Pennsylvania, acquiring all the patent rights, stock, and machinery, and is now manufacturing the products of that Company. A recent bulletin of the Company is devoted to the all-metal hose, connections, couplings, etc., manufactured by this Company.

ANTIMONY, as shown in our editorial of this week, is marketed more by brand than quality. This suggests that a local smelter might develop a good business by 'establishing a brand.' This requires capital, energy, and time, but a good selling brand of any standard product is well worth effort.

COMMUNICATIONS regarding the California Metal Producers Association may be addressed to 1022 Crocker building, San Francisco, for the present. It is expected that permanent headquarters will be established in a short time. We print this week the by-laws of the new association which are of interest not only locally but, being based upon experience in Nevada and elsewhere, as offering a model for similar organizations in other states.

GOLD RESERVES of the Bank of England and the Bank of Germany continue to increase, in spite of the war. Those of the former institution amount to £69,500,000, against £38,131,544 on July 30. It is probable that part of the present holding is in its branch at Ottawa, Canada. The sum of $8,000,000 left New York for the bank at Ottawa on November 9. The Bank of Germany has now M.1,826,094,000 in gold, about M.480,000,000 above the reserve of July 25. Of this increase, M.200,000,000 is from the war chest in Spandau Castle, having been recently removed to the Reichsbank.

GRANTING, by the United States Supreme Court, of the petition of Minerals Separation, Limited, for a writ of certiorari directed to the Ninth Circuit Court of Appeals, announced last week, has the welcome effect of bringing flotation litigation directly before the final court. It may be true as has been jokingly stated that "the supremeness of the Supreme Court consists mainly in the lastness of its guess," but at least its decision does settle things. So far as the mining and metallurgical profession is concerned, that is the thing chiefly desired as regards rights to flotation processes. In view of the conflicting decisions that have been given it would be idle to speculate as to the possible result of the new hearing, but even getting the matter before the court is a notable triumph for the counsel for Minerals Separation, since we believe that only about two per cent of such petitions receive favorable consideration.

AMERICANS doing business in other parts of the world are often at a disadvantage owing to the absence of American banking institutions, and this has been particularly true of South America. The formal opening of a branch of the National City Bank in Buenos Aires under charter of the government of Argentine on the tenth of this month will, therefore, be welcomed by many American manufacturers who have been trading with our Latin-American neighbors.

SINALOA and the west coast of Mexico are showing signs of a reawakening of the mining industry and a general feeling of optimism prevails among the mine operators. While there is no general boom, there is a feeling among those who have weathered the storm, that quiet waters are not far off. It may seem strange to many on this side of the Rio Grande, but it is true, that the west coast country, as do central and northern Mexico, looks to Francisco Villa as the best solution of the peace problem and believes that a *Constitucionalist* candidate with Villa's support is the logical hope of the people. This uncouth peon of Chihuahua, as he has been represented to the American people, holds the confidence of a large percentage of the Mexican people, and with the *Ejercito Constitucionalista* supporting his cause, is believed by many to be the best able to bring about a national peace. The west coast country with its numerous *minerales* has by no means been in a state of innocuous desuetude, and a limited production has been maintained throughout the recent years of revolution. Handicapped by lack of railway transportation, by bandits, by revolution, and by the general state of unrest, there, nevertheless, have been a few who have stuck to their work, and to these and others who are making efforts to recoup their losses, we extend our best wishes for a speedy return of peace and the blessings which go with it. It is gratifying to note that the west coast country is not suffering from a shortage of labor, as in the north and central part of Mexico, where Villa's call to arms has greatly depleted the ranks of the miners. While exchange rates have gone down, there has not been a corresponding increase in the cost of commodities and labor, and it is a consolation to the operators who have been able to continue at the mines to see this reflected in the mining costs. Lower costs prevail at the present time, when considered in terms of gold currency, than during the days of peace

and plenty. The present delicate political situation was heavily discounted in advance, and it is hoped that it will soon give way to the establishment of a government which will be representative of the majority, and then the long-looked-for prosperity may become a reality.

MINE OWNERS AND THE CALIFORNIA INDUSTRIAL ACCIDENT COMMISSION

Discussing the situation in California as regards mine owners and workmen's compensation indemnity insurance in January, we pointed out various reasons for believing that the rates charged for such insurance were entirely too high. Following this, we circularized our friends in the state and obtained important data regarding the volume of business and the rates actually paid, which we printed July 11. It was shown that the actual rate, while lower than the open rate, was still materially above the amounts paid elsewhere, and, admitting the inadequacy of existing records, far above the probable real cost. Since we first investigated the subject, relief, in part, has come through the organization of the Mine Owners' Casualty Indemnity Exchange, a coöperative institution designed to afford insurance to its members at approximate cost. We are glad to be able to say that the Exchange has found substantial support and shows every probability of affording real help to its members. Many California mine owners, however, take the ground that the state, having got them into the difficulty, should find for them a way out. This feeling is all the more keen since through the State Compensation Insurance Fund, other industries are given protection at cost, and the further fact that miners, while facing increased costs of both labor and supplies, cannot add to the price of their principal product, gold. We have conferred frequently with the Industrial Accident Commission, and have found its members and employees alive to the difficulties of the situation and willing and anxious to lend any aid that may prove feasible. As a first step a conference with mine owners was held last week at which the whole situation was informally but thoroughly discussed. The attendance, while not large, was especially representative, and the purpose to coöperate in finding a way out found expression in the appointment of a committee to formulate a plan which the Commission may consider for recommendation to the legislature. This committee consists of Messrs. George W. Starr, of the North Star Mines Company; Newton Cleaveland, of the Yuba Construction Company; D. E. Hayden, of the Wisconsin North Fork gravel mine; C. W. Fellows, manager of the Insurance Department, Industrial Accident Commission; and Chris. M. Bradley, attorney for the Commission. It is hoped that this committee may be able to formulate a plan whereby the Commission may organize and manage a mine owners' mutual. It was brought out at the conference that the cost for salaries and expenses amounted to but 9.37 per cent of the premiums received by the State Insurance Fund in the first nine months of its existence, and that a refund averaging 15 per cent would be allowed policy holders. Against this, private companies load compensation insurance 40 per cent to cover the cost of doing business. Mr. Cleaveland announced that an insurance exchange maintained by the metal trades, had resulted in a saving of 50 per cent in premiums. Mr. Starr stated that at the Empire mines, applying the present law to the accident record of 30 years, it was estimated that the cost would be about 2½ per cent. The amounts paid this year have been materially less. Experience from other mines was also given, and Mr. Albert Burch spoke most informingly upon the operation of the Nevada law.

In Nevada the largest single industry is cattle raising, but the largest employers of labor are the mines. Of the premiums paid for workmen's compensation insurance, 90 per cent is paid by the mining companies, and more than 86 per cent by members of the Nevada Mine Owners' Association. The executive committee of the latter has therefore followed the conduct of the business with great care. Starting without capital and with an average rate of 2.2 per cent (the Nevada Consolidated company as the largest employer being allowed a special rate of 2 per cent), the fund has paid all adjusted claims, set aside money for those not yet adjudicated and for future payments on claims allowed, kept expenses down to 10.6 per cent, and is building up a surplus. Allowing for the difference in compensation provided in the two states, and for medical attendance at the Nevada cost, Mr. Burch estimated that insurance in California ought not to cost more than 4 per cent, average rate, as against the 7.86 per cent asked. Mr. Fellows questioned this estimate, the main difference being in regard to cost of medical attendance. In Nevada the mines are so grouped that central hospitals are largely possible. The men are charged $1 per month, which covers hospital and medical attendance for both themselves and their families. This amounts to about one per cent of the pay roll. In California, medical attendance is required under the law, and the mines being scattered, central hospitals are rare. While only a part of the men injured receive compensation, they all receive medical attention, and evidently the individual fees amount to more than the whole hospital expense in Nevada. Indeed, the Commission pointed out that even in the general industries insured by the state, more money was paid out for medical attendance than for compensation. The Commission takes the ground that the best possible compensation to an injured worker is to put him back into the same condition, or as nearly the same as may be possible, as he occupied before the accident. This is a stand that will be approved by all, but the difference in cost as between Nevada and California raises the question whether economy is not possible in this particular in the latter state. This and other questions are receiving earnest attention from the committee that has been appointed to formulate a plan of action, and there is every prospect that acceptable recommendations will result.

ANTIMONY

To be of much use in industry a metal must be tenacious; in other words, strong and ductile. This is well illustrated in the case of iron, the most useful of all metals, although it is so easily attacked by atmospheric agencies that special means have to be taken to protect it from corrosion. Other qualities are of great importance also, and give to the other metals their special fields of usefulness. But antimony is the ugly duckling of the metallic family, and its qualities are such that, although it occurs in abundance in nature, it is used but little in industry. It is brittle, and though harder (and presumably stronger) than copper it is of no use for engineering purposes in the metallic state, since objects could only be made from it with difficulty and would break at the slightest blow. It is not affected by exposure to the atmosphere or by sulphuric acid, while hydrochloric acid attacks it but little. It has a pleasing color, and many other good qualities, but its lack of toughness is its fatal defect.

Antimony may be regarded as a recent metal, for although its minerals were known to the ancients, the metal itself seems to have attracted but little attention, as is indicated in the historical note on the metallurgy of antimony, by Mr. H. C. Hoover, in 'De Re Metallica.' Indeed, until a demand for a hardening addition to lead was created by the discovery of the art of printing from movable type, it may be said that there was little use for antimony, though it was used to some extent in the making of the alloys from which common grade household utensils of the Middle Ages were cast. The empirical metallurgists of those days soon found that when various other metals were added to tin the resulting mixture was easier to fuse, ran better in the molds, and was harder and more tenacious when cold. Of recent years it has been learned that such mixtures of metals produce eutectics and intermetallic compounds, but the earlier workers obtained the desired results by the less scientific but effective methods of empirical experiment. In the early days of the nineteenth century a clever American mechanic and inventor, Isaac Babbitt, who like others had struggled with the difficulty of placing the bearings of a rotating shaft in a straight line, conceived the idea of using a recessed support and casting the bearing around the shaft to a perfect fit. For this purpose he used pewter, which contains about 7 per cent antimony and nearly 90 per cent tin. Further experiment showed that for fast-running shafts an alloy of tin, lead, and antimony is more satisfactory. The tremendous development of the art of machinery construction, during the past half century, has created a large demand for such bearing alloys, and their properties and composition have been carefully studied by mechanical engineers and metallurgists. The use of pewter and similar alloys in domestic economy has greatly declined, having been successively supplanted by tinware, enameled ironware, and aluminum, and the making of fittings for coffins is the only considerable purpose for which they are now employed. But in some foreign countries, notably Japan, such alloys are still extensively used.

It is thus seen that while antimony has a number of uses (several minor ones not being here enumerated) the quantity required is not great, the total consumption in this country during 1913 having been less than 13,000 tons. This may be compared with the nearly 500,000 tons of lead consumed in the same period. The average selling price of antimony is about double that of lead, though it probably occurs quite as abundantly in nature as does lead, and its metallurgical recovery offers no especial difficulties. The comparatively small and rather fluctuating demand restricts most of the producers to a rather small scale of operations, and so makes operating costs higher. In addition, the selling of antimony is on a different basis from the selling of lead. This may be indicated by comparing them to the selling of flour and pepper. Flour is needed and sold in enormous quantities, standards of quality are well established, and competition in selling is chiefly in prices, while pepper is sold in small packages, competition being chiefly in presenting the product to consumers in attractive form. The baker who uses flour by the ton is tremendously interested in a possible saving of a quarter of a cent per pound; the householder who uses a few ounces of pepper per month cares nothing for a cent or two per pound, considering only whether it exactly suits his requirements. Thus, for example, Cookson's antimony sells for about $30 more per ton than Chinese brands, a margin for which the copper or lead producers would willingly go to almost any lengths of refining.

For the reasons which have been indicated, the production of antimony is not very profitable unless it is associated with some other metal. Since the antimony is not used by itself, but is commonly alloyed with lead, the frequent occurrence of antimony in lead ores is a decided convenience. Some of the antimony is doubtless lost in fume in smelting the lead, but much of it goes into the base bullion. Before the base bullion is subjected to desilverization, it is 'softened' in a reverberatory furnace, and the antimony, together with lead, is removed in the form of antimony skimmings, which are put aside for periodic reduction to antimonial or hard lead in an ordinary lead-smelting furnace. This method of procedure is subject to the disadvantage that arsenic also occurs in base bullion, and while much of it is removed as arsenic skimmings before the antimony skimmings rise, the separation is incomplete and the antimonial lead contains some arsenic. This is no drawback for many uses, but the makers of bearing metal and the type founders prefer to buy pure metals and alloy them, thus obtaining exactly the product desired and also making less dross in their operations. For this reason, more than half our antimony consumption is of pure metal, which is all imported, and the (supposedly) purer grades of the metal command higher prices. Cookson's brands are more in demand than Hal-

lett's, and both command better prices than the Hungarian or Chinese antimony. The average New York prices for the past seven years have been as follows, in cents per pound:

	1907.	1908.	1909.	1910.	1911.	1912.	1913.
Cookson's	17.03	8.57	8.27	8.24	8.58	8.54	8.52
Hallett's	15.39	8.37	7.98	8.00	8.16	8.19	8.07
Hungarian	14.68	7.80	7.35	7.27	7.48	7.63	7.43

The average price of Chinese brands is not available, but is usually about 1½ cents less than Cookson's. It is an interesting feature of this situation that careful analyses recently published by Mr. W. A. Cowan in the *Transactions* of the American Institute of Metals, show that although Cookson's antimony is purer than Hallett's, the Chinese Hwachang antimony is purer than either. Recently Hallett's antimony has been most in demand, and the inference seems inevitable that antimony is sold on the basis of its trade-mark rather than its quality. Antimony crystallizes in the hexagonal system, and if allowed to cool slowly from the molten state the surface of the metal is covered with large 'stars' which are popularly supposed to indicate that the metal is pure. This appearance actually indicates only that the metal was slowly cooled, since the least pure of commercial grades can be easily made to produce 'stars' by proper treatment. Nevertheless, only the 'star' antimony is accepted in the market as pure.

There are many other contradictory things in the metallurgy of antimony, and not the least is the peculiar use of terms. Stibnite, Sb_2S_3, is the mineral from which antimony is obtained, and as this is easily fusible the first operation is the liquation of the ore, usually in pots, the fused stibnite being allowed to run off from the gangue. It is collected and cooled, and is then known as 'crude antimony,' instead of antimony matte, which would be the logical name for it. The next step is the elimination of the sulphur. This is done by roasting to oxide and then reducing with charcoal, by fusing with scrap iron, or by electrolyzing a solution of the 'crude antimony' in fused sodium sulphide. The metal thus produced is known as 'antimony regulus,' a most confusing term to the ordinary metallurgist, who seldom uses the term regulus, which he regards as synonymous with matte. Regulus was the name given to antimony by the medieval alchemists because it alloys readily with gold, which they regarded as the king of metals. By extension, the term was applied to any metallic mass which separates from slag in smelting operations, and finally to the matte produced in smelting. The term has long since outlived its usefulness.

As already remarked, there are plenty of antimony deposits in the world. The largest and most cheaply worked are those in China, occurring throughout the large area south of the Yangtze river, but especially in Hunan and Kuangtung provinces. In the past decade a number of smelting plants have been established, and the output of China has increased from an insignificant fraction of the world's output to about 60 per cent of the annual production. In spite of this, so far as can be learned, none of the operating companies in China have made much money, and most of the hundred or more Chinese companies are generally in financial difficulties. The best known of all the antimony mines is La Lucette, in France, which proved to contain gold in its deeper workings and made good profits. This mine is now practically worked out. There are numerous other antimony deposits throughout the world, and in this country they occur in Nevada, Arkansas, Idaho, Washington, California, Utah, and Oregon. None of these deposits can be as cheaply worked as those in China, and as the freight rate from Shanghai to New York is only $8.75 per ton, it is easily seen that mines in the Rocky Mountain states could scarcely hope to compete for the New York market, more especially as there are no antimony smelters now in operation in this country.

The outbreak of the European war caused antimony to take a sharp upward rise, as the war interfered with shipments and gave rise to a greatly increased demand, since considerable quantities of antimony are used for alloying with lead to make bullets for shrapnel. Shrapnel, as probably everyone knows, is a shell filled with bullets and provided with a bursting charge of explosive. At the proper point in its flight the shell explodes and the bullets are thrown out, spreading out so as to sweep an area of about 250 by 30 yards. These bullets should be brittle, so that they will break up to some extent and therefore sweep the area more effectively, and this brittleness is produced by alloying the lead with antimony. The rapid consumption of the stock of prepared ammunition makes it necessary for the European governments to manufacture more, while the recent agitation in Congress over our own military unpreparedness is likely to lead to increased manufacture in our own arsenals. Just before the war, prices here were about normal, although the stocks of the metal were only about one-third of what they had been a year before. For a time prices went to high figures and they still remain high; Chinese antimony having ranged from 9 cents per pound to 14 cents per pound during October, and averaging about 11½ cents. As long as the war continues, the demand for antimony will be greater than normal and prices will rule accordingly, but after the war they are likely to decline sharply, since the output of the Chinese mines can be, and doubtless is being, greatly increased. The increased production will come on the market at a time when the demand is slackening, so that the average price in the next few years is more likely to be under than over the average of recent years. It is clear, therefore, that there is nothing in the present situation to encourage the development of antimony mines in this country, since the present high prices are extremely likely to prove only temporary, and there is much danger that operating profits will not repay the investment necessary before prices decline to a point at which antimony production in this country is unremunerative.

Welfare Work Among Mine Workers

By L. F. S. HOLLAND

The provision of good board, lodging, medical treatment, and means of recreation for mine workers is no longer regarded by wise managers as philanthropy or paternalism, but as good business. The methods of attacking the problem of obtaining efficiency from the labor available differ in various localities, according to local conditions; but for good results, it may be accepted as essential that the workers be kept in good physical condition. The Michigan copper and iron miners get a larger proportion of their remuneration in the form of such betterments as cheap dwellings, sick and accident benefits, pensions, etc., than do workers in, say, the Butte, Montana, district, where the tendency seems to be to pay the highest wages that can reasonably be afforded directly to the men, and let them shift for themselves when their day's work is done. Some of the Butte companies, however, provide excellent change and wash houses at the mines.

SMUGGLER UNION BOARDING-HOUSE AND SURROUNDINGS.

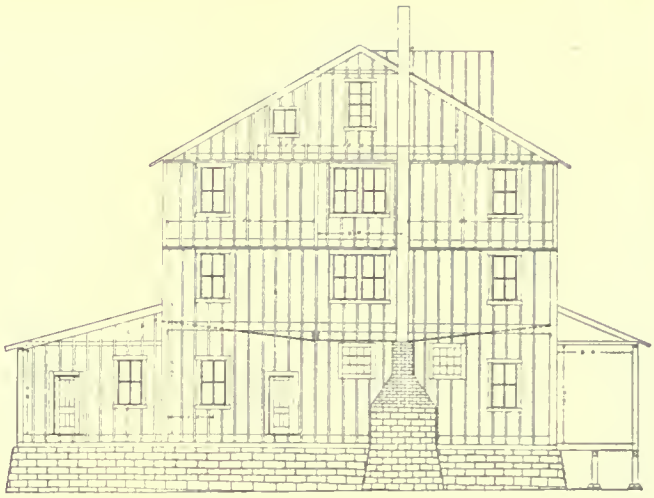
However well a company may treat its men in welfare work, it will not necessarily be free from labor troubles, as witness the Calumet & Hecla company, which has always treated its men well, and the Colorado Fuel & Iron Co., which has spent many thousands of dollars every year in betterments. Besides the Lake Superior and Colorado districts, Butte also has had its grief. Where the Western Federation of Miners and its affiliations have shown strength, labor troubles have resulted, and with similar opportunities, similar results may be expected. Mother Jones does not draw $42 per day in times of peace. Generosity in expenditures for welfare work does not protect a company from professional agitators, but in any given district where wages are approximately the same at all the mines, the best accommodations naturally tend to attract the best men.

It happens frequently that by reason of the isolation of a mine, the operating company has to maintain a boarding-house to accommodate nearly all of its employees. Sometimes such accommodations are of the crudest description, and are found to consist of tiers of bunks built of rough lumber, frequently infested with vermin; dirty tin basins or wooden troughs to wash in; no baths; horrible back-houses; and an abundance of food poorly cooked. The best that can be said of such 'company' accommodations is that they are better than those tolerated by the men who 'batch,' or those provided by padrones.

A case in Colorado is on record where a padrone provided for 38 Italians a filthy bunk-house whose dimensions were 40 by 15 ft., with two small windows. The men slept in two shifts and they ate their meals in a small lean-to where the cooking was also done, by the padrone himself. Although they were getting $3 per day, the men were willing to tolerate all this, but the high percentage of sickness among them, and their unreliability and inefficiency, drew attention to their living conditions. The company then took steps to put the padrone out of business as a boarding-house keeper.

In his book, 'Across the San Juan Mountains,' T. A. Rickard says of the coffee supplied by the average mine cook: "It is a concoction out of keeping with the excellence of the remainder of the miner's fare and much better adapted for staining floors and removing boiler-scale." While the coffee served in the San Juan boarding-houses perhaps generally remains the same fearful and wonderful 'dope' found in most mining camps, there have been notable improvements in other respects at some of the larger mine boarding-houses, such as the Tomboy, Liberty Bell, and Smuggler Union mines, near Telluride, Colorado.

In consequence of a fire which wiped out all the old boarding and bunk-houses at the Bullion Tunnel workings of the Smuggler Union mines, I was called upon to design and erect a new house to accommodate a maximum of 200 men. The house had to be built in the depth of winter at a time when the railroad and county roads were under repair after a disastrous flood. Some necessary supplies were unobtainable within hundreds of miles. The truss-rods, for example, were delivered several weeks after the house had been built, on posts. As for carpenters, with the exception of a good boss carpenter and an able assistant, few of the men in the neighborhood who were hired as carpenters could saw a board straight. The total cost of the house was approximately $30,000. In summer time and with normal conditions as to deliveries and labor it could be duplicated for one-third less.

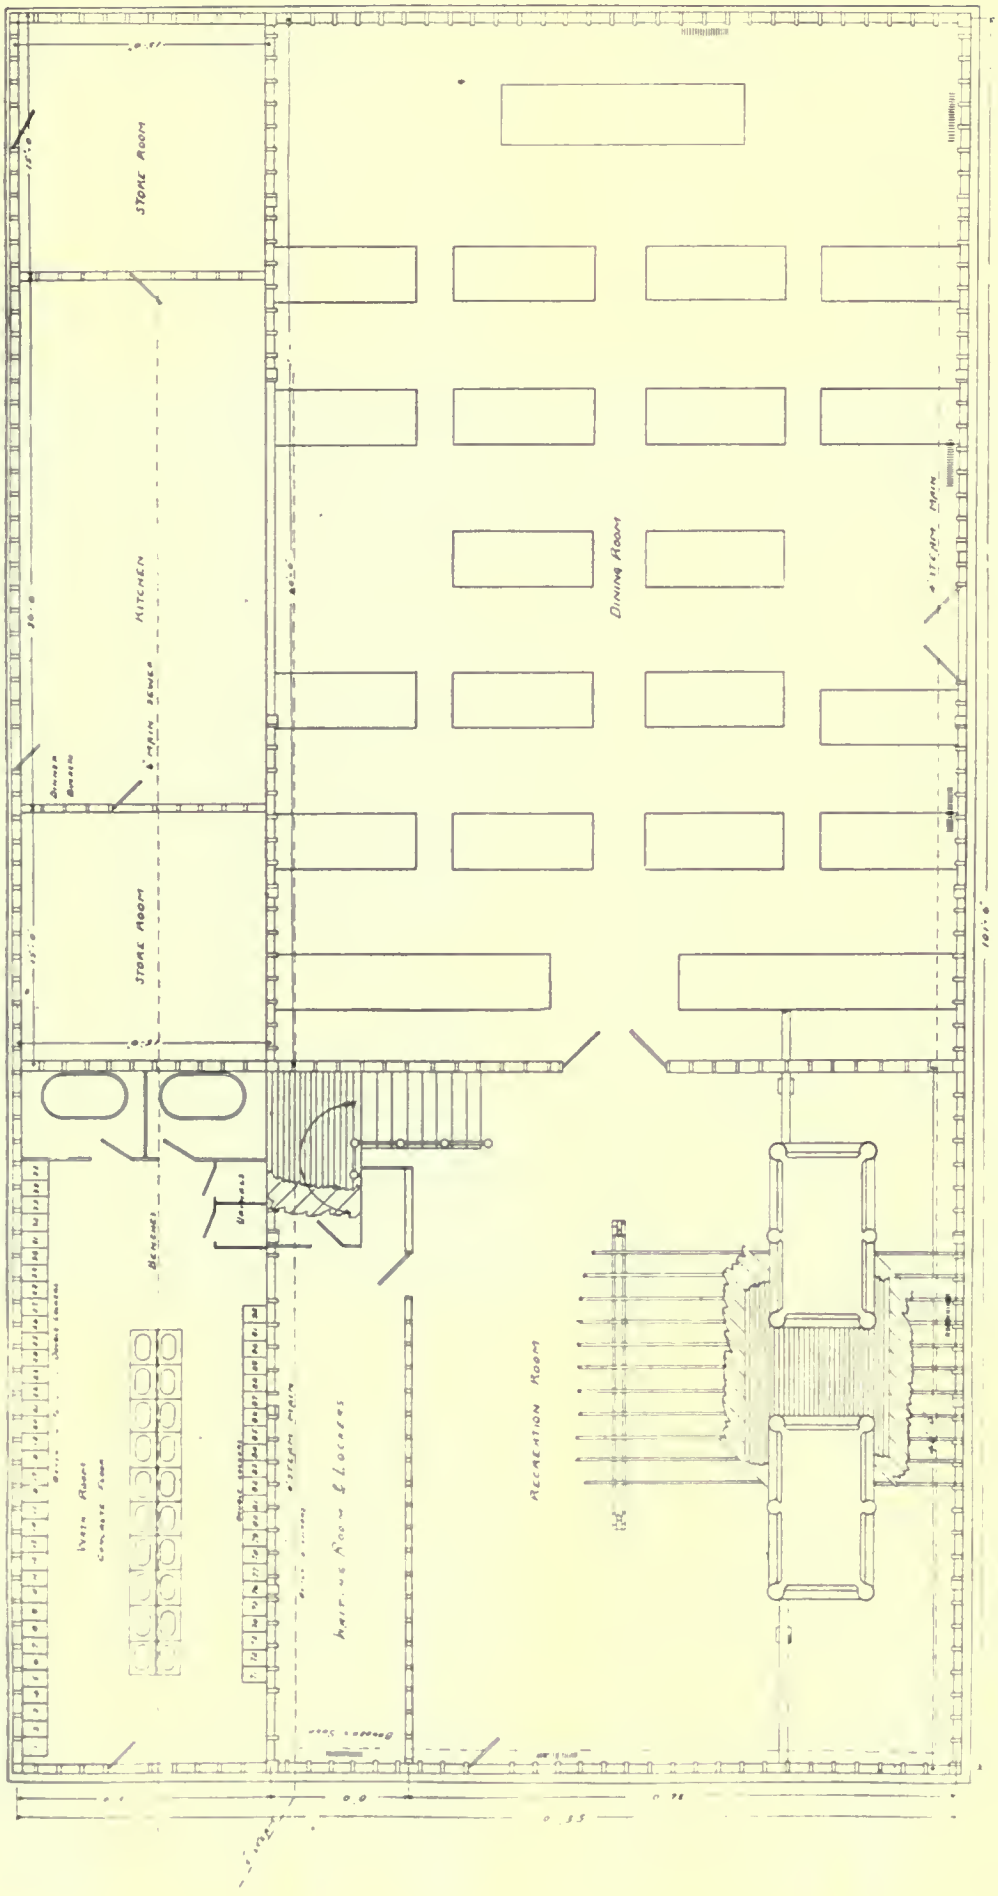


END ELEVATION.

In designing this house, advantage was taken of information gained in many mining camps, and especially of our good neighbors' experience with their new houses. The Smuggler house has now been operated long enough to demonstrate its general success. In these notes, with plans and photographs, I will endeavor to indicate wherein innovations have been successful and where unsuccessful in attempts to better the conditions of mine workers.

It is important to consider the type of men for whom betterments are provided, and what are their opportunities. 'Labor' in a mine nowadays usually means the man from Europe. The happy days are gone when a Western mine crew consisted mainly of 'Cousin Jacks,' 'Miekeys,' 'Bobtails,' and 'Bluenoses.' Many of the best of them have been driven out by the methods of the unions which have done their utmost to discourage efficiency. The following is the percentage of nationalities making up a typical crew I had working under me last year at the Smuggler Union while I was superintendent of mines: Italians and Italian-speaking Austrians, 30%; Swedes and Finlanders, 21%; Greeks (mostly

SIDE ELEVATION OF BOARDING-HOUSE.



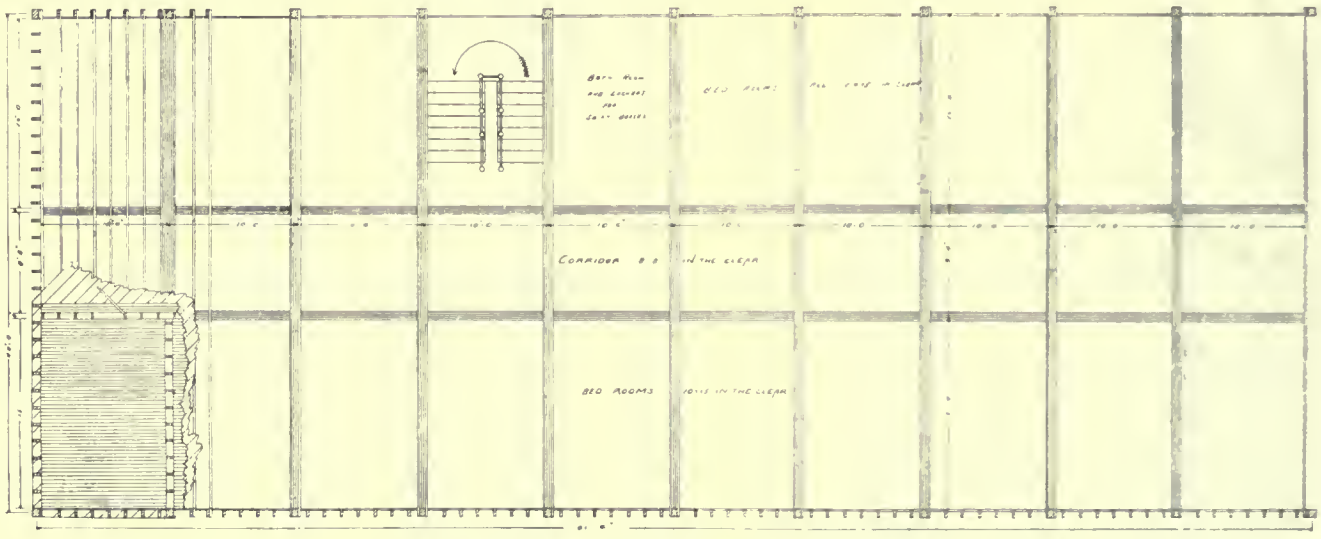
FLOOR PLAN, SHOWING KITCHEN, STORE ROOM, DINING-ROOM, WASH- ROOM, AND RECREATION ROOM, WITH STRUCTURAL DETAILS.

from Crete), 16%; Americans, 13%; British (mostly Cornishmen), 10%; various nationalities, chiefly Slavs, 10%. Only a small proportion of the foreigners will ever become American citizens. Other than shift-bosses, few trained miners were found among the Americans, who generally favored 'outside' jobs, nor did the Americans generally set a shining example to the foreigners in sobriety, efficiency, or recreations. The lowest rate of pay in the district is $3 for eight hours' work. Machine men and good timbermen usually get $4, and shift-bosses $5. The charge for board and lodging in the companies' houses is uniformly $1 per day, and a small fixed monthly charge is made for medical and hospital treatment.

The high rate of wages and steady operation of the larger mines naturally attract many efficient men to the district, but they also encourage unskilled and ignorant employees to undertake duties and risks for which they are not fitted. An employment agent has sent me men for underground work who could speak no English and had never worked in a mine. When the choice lies between an anarchist who can break ground besides taking care of himself, and a perfectly well behaved young man whose true calling is the shoe-shining parlor or the peanut stand, a mine superintendent with both eyes on the cost of production, and perhaps struggling to make a losing property profitable, will commonly prefer to take a chance on the anarchist.

The elevation of the mines, 11,000 to 12,000 feet above the sea, is not conducive to overexertion, especially out of working hours. The mine workers often seek entertainment at the local 'boot leggers' or 'blind pigs.' Except as a result of a stabbing affray or other serious trouble, the county authorities, in my experience, can rarely be persuaded to prosecute illicit liquor sellers. Amusement is also sought, especially after pay-days, in the town of Telluride, four or five miles down hill. The round trip by saddle-horse costs $2. The town is 'wide open:' that is, an abundance of saloons, brothels, and professional gamblers invite the visitors at every turn to waste their money so long as they have any to spend. A conscientious sheriff has been known to seize some of the public roulette and faro layouts, but he got little assistance from the legal authorities, nor was he nominated for reëlection. About the only rational entertainment provided in the town for the mine worker is the moving-picture show and an occasional baseball match.

In spite of the illegalities, the crowd, on the whole, is comparatively well behaved, and requires only a small police force to keep it in order. It is a matter of perspective. In a community where a self-confessed assassin can murder a mine manager by shooting him in the back, and then be acquitted by a jury of his peers; and another mine manager who has done great public service and would be a credit to any community, is dynamited in bed, without any penalty to the would-be murderer, the operation of a roulette wheel or faro bank seems a very unimportant infraction of good conduct.



PLAN OF A BEDROOM FLOOR WITH STRUCTURAL DETAILS.

The president and directors of the Smuggler Union Mining Co. are men who have ever shown a lively sense of responsibility toward their employees. That it is not entirely a matter of commercialism is indicated by the fact that they have generously treated their men in the matter of the new boarding-house and other betterments although the expectation of life of the mine was only a few years. Bearing in mind the local conditions as to entertainment above mentioned, a large 'recreation room' was provided in the new house, with pool tables, card tables, reading tables, and a big open fireplace for cheerfulness. At the elevation of the house, about 11,000 ft. above the sea, snow may fly any day in the year, so steam radiators were provided besides the fireplace. The steam-heating plant is outside the house, and is an old one not destroyed by the fire which razed the other buildings.

The Company maintains a fine library at its mills at Pandora, and issues printed catalogues. Books are freely loaned to any of the employees applying for them,

either at the mine or mill; but few of the miners, even the English-speaking ones, avail themselves of the privilege. A few foreign newspapers are provided by the Company, and these seem to be more appreciated than the books.

A few years ago, the Young Men's Christian Association attempted some welfare work at the Tomboy and Smuggler Union mines, to which the mine managements, besides the men, gave generous financial support. The Companies provided suitable buildings, bowling alleys, and other means of recreation, besides a monthly cash contribution. Among other educational aims, it was hoped to teach some of the foreigners English. The intentions were good enough, but after some months' trial, the whole scheme seemed to fall into disrepute and to lose the support of the men, chiefly, I believe, because the particular representatives of the Association who were sent to take charge of the work happened to be poor selections, and were unsuitable for the job. The Smuggler equipment was burned in the fire; in fact, that is where the fire started. In the new house, bowling alleys were not provided, as it was found that the men generally very much preferred pocket billiards. If desired, however, bowling alleys might be placed in the basement without danger of annoyance to occupants of the bedrooms in the upper floors.

The accompanying photograph of the Smuggler Union dining-room shows that tables and chairs for eight men each have been substituted for the usual long tables and benches. Besides adding to the comfort of the men and to the appearance of the room, the change has been found to facilitate service and cleanliness. The wooden chairs used all over the house were strengthened by wiring, but the breakages have been many. Suitable metal chairs, which should be more durable, can now be bought in Chicago for $1.50 each retail.

BILLIARD ROOM, DINING-ROOM, BEDROOM, AND LOCKER ROOM, SMUGGLER UNION BOARDING-HOUSE.

Serving tables are conveniently placed between the kitchen and dining-room, and gangways are arranged so that the 'flunkeys' can get around easily and quickly. The kitchen is provided with such labor-saving appliances as a steam-table, tea and coffee urns such as are used at railroad lunch counters, and motor-driven coffee grinder and meat mincer. A track behind the kitchen from the head of the aerial tramway, over which supplies are brought from the railroad, allows coal, groceries, and meats to be unloaded from trucks at the proper places. A half-door at the back of the kitchen allows the men to hand in their dinner buckets as they come out of the mine without having to pass through clean rooms in muddy boots and clothes.

After handing in their dinner buckets, the men can pass directly to the wash-room, in which are provided

20 white enameled stationary wash-basins with hot and cold water and self-closing faucets. Around the room, which has a concrete floor and drains, are ranged double-deck steel and wire lockers, as shown in the illustration. Steam pipes under the lockers dry the clothes left in them between shifts, but as the mine is not very wet except underfoot, no great amount of heat is required for the purpose. At very wet mines, the method sometimes employed for drying and storing clothes by suspending them from the roof of the 'dry' room may be adopted with advantage. A galvanized iron chain having at its end a hook on which hang the clothes, towel, soap-box, etc., passes over a pulley in the roof, and the chain is secured by a padlock, so that the men cannot tamper with each other's clothes.

The space between the wash-room and the recreation room is occupied by additional lockers which could not be accommodated in the wash-room. This space is also used as a waiting-room for men in their 'digging' clothes, about to go on shift, and it also accommodates a barber-shop. Among the dining-room staff is usually found a licensed barber who is given free use of the shop in consideration of the convenience to the men. Otherwise a barber from town makes periodical visits.

Experience with the old house which was burned showed that, for some unexplained reason, the men did not take kindly to the eight shower-baths provided there, but that the one bath-tub was well patronized. In the new house, three bath-tubs and two showers, each with hot and cold water, were provided, but the showers are much less used than the tubs. A private bath and toilet room, with enough lockers, are provided for the shift-bosses on the second floor, as is a private sitting-room for them. It may be that an elaborate equipment of shower-baths in white glazed tile cubicles, such as Messrs. Brunner, Mond & Co. have provided at their works in Cheshire, England, might cause the shower-bath to become fashionable at Smuggler, but evidently it is not so at present. Showers are much more economical with water than are bath-tubs, and at many mines clean water is scarce enough to be an important consideration.

Connected by covered way behind the wash-room, but entirely separate from the main building, are housed the closets, which are flushed automatically from the seats. The floor is of concrete and the janitor can quickly wash out the whole place with a hose. For thrifty men who do their own washing, enameled iron laundry trays are provided in this separate building. Urinals are provided on every floor of the main building, as are slop sinks with hot and cold water to enable the janitor to take care of the cuspidors. It may be noted that one janitor takes care of the whole house and keeps it clean.

In all mine boarding-houses preparations should be made to drive out the unwelcome but ubiquitous visitor called various names, but never anything complimentary, such as *cimex lectularius*, Norfolk Howard, or (adjectival) bedbug. The female of the species deposits eggs at the beginning of summer in crevices of wood and other retired situations, and it is said that new frame buildings which have never been lived in by human beings are sometimes infested with the pests. In one large mine boarding-house with which I am acquainted, whose bedrooms had been nicely finished with beaded ceiling, the inhabitants in the beading became so prolific and unmanageable that it finally became necessary to cover the partitions, etc., with canvas and calsomine the canvas. A mixture of two gallons of coal oil, one gallon of turpentine, and four ounces of pennyroyal, applied with a gardener's spray, will generally drive out the pests. In the new Smuggler house the material chosen for all inside wall and ceiling covering was 'Beaver Board,' which presents a smooth surface in large sheets, and takes a good coat of paint. The only lodgment which insects can find is between the sheets, and these cracks are usually covered with strips of wood. In spite of a thorough drying in hot rooms, the sheets were found, after being applied to the walls of the bedrooms, to shrink and to pull away from the nails, leaving unsightly gaps, and affording good lodgment for insects behind the one-inch strips of wood. The difficulty was finally overcome by taking off the wooden strips shown in the illustration of the bedroom and gluing strips of thick cotton sheeting over the joints between the sheets of Beaver Board. In the dining-room and recreation room downstairs, where no protection from the pests was found to be necessary, the walls and ceilings were attractively paneled by nailing 3 and 4-in. strips of wood over the joints and decorating wood and Beaver Board in harmonious colors.

For adequately supporting the sheets of Beaver Board a large amount of 2 by 4-in. 'cripples' was found necessary in addition to the studding. Where extra warmth is desired, it might be well first to cover the inside walls with rough one-inch boards and nail the Beaver Board to them. In damp situations, the sheets were found to warp badly. There are other similar compositions, such as 'Bishopric Board' and 'Sackett Board,' which might be less subject to this warping, and at the same time be more fire resistant, but they usually come in smaller sheets and are more expensive.

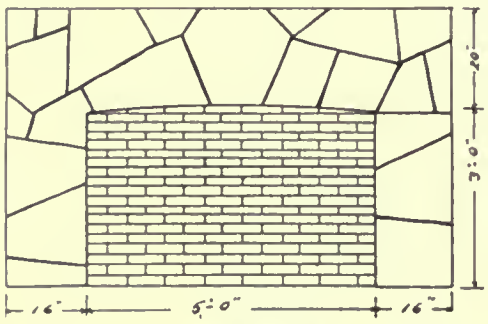
The type of bedstead adopted was a white enameled iron double-decker. There being two bedsteads in a room, each of four men has his own single bed. Mattresses are provided by the Company, and the men at the mine provide their own blankets, which are fumigated with formaldehyde before being allowed in the house. At the mill boarding-house at Pandora, the Company also provides blankets and bed linen. There is no logical reason for the discrimination except that such has always been the custom.

Each bedroom in the Smuggler house is provided with a steam radiator of suitable size, but during the first season it was found that steam heat in the bedrooms led to epidemics of colds. Except on very cold and stormy nights, the bedroom radiators are now kept cold, with better results to the men. The great danger at the high altitudes is pneumonia, epidemics of which

sometimes become very virulent. It happens that nearly every fatal case I have known occurred immediately after the victim had been on a 'spree' in town, when perhaps his vitality and powers of resistance were lowered.

A small temporary detention hospital, with a resident physician, occupies a separate building next to the boarding-house. Serious cases of sickness or accident are transferred, as soon as convenient, by horse ambulance, or by stretcher over the aerial tramway, to a larger hospital in town, to which nearly all the mines send their sick and injured. Sometimes better medical service can be obtained at a mine by having a resident skilled trained nurse who can obtain the attendance of a skilled physician at short notice, rather than by having to rely entirely on a young physician, perhaps a recent graduate, of the kind likely to be found at an isolated mine, where there is no opportunity for building up a profitable practice. It is, however, difficult to get a skilled trained nurse to stay at an isolated mine unless she happens to be married and her husband has employment at the mine.

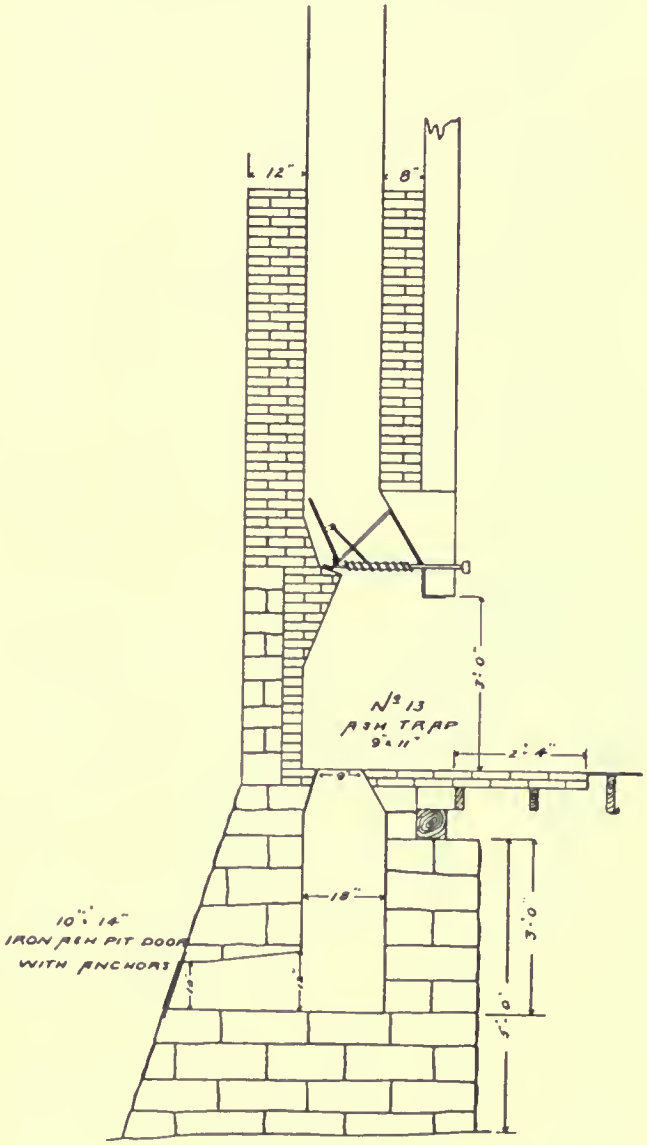
The rules forbid the bringing of liquor into the Smuggler boarding-house. Those who desire it, however, can generally get more than is good for them at one of the 'blind pigs' in the immediate neighborhood, or at the many saloons in town, as already described. In some mining camps, efforts have been made to regulate the sale of liquor with some success. Prohibition has always failed, I believe, but the 'restricted club' idea,



THE FIREPLACE

such as John C. Osgood worked out at the Coalbasin and Redstone Clubs for employees of the Colorado Fuel & Iron Co., is worthy of trial in localities where conditions are suitable. The essentials for success seem to be that the club should have a monopoly of the sale of liquor in the camp; no treating to be allowed; no drinks to be sold to a man who shows signs of intoxication; and all charges to be paid for at the time they are incurred. A club with a similar system has been in operation at the Cactus copper mine, near Milford, Utah. At my last visit, Mr. Heidenreich, the mine manager, informed me that the club was very successfully fulfilling its mission. At all these clubs, cases of drunkenness are said to be rare, and an offender is not given the opportunity of repeating the offense in the club.

These are the humane aspects of betterment work as well as commercial considerations. It has been said that a corporation has no soul, but if it acts with fairness and justice to its men, and gives them opportunities for health and recreation while earning fair wages, it may be credited with an excellent substitute for a soul.



CROSS-SECTION OF CHIMNEY AND FIREPLACE.

There is not much encouragement for sentiment in dealing with a crowd of foreigners whose principal object is to quit as soon as they have saved enough money for their purpose, which is generally to go back to Europe. Welfare work costs money, but it is doubtful if any company was ever a loser in the end by spending money for such a purpose.

WOLFRAM produced in Siam totaled 309 tons in 1912-13. On the east coast the Chinese had separated this mineral from tin and left it in heaps as valueless. The surface workings are nearly exhausted, and capital is required for the deeper formations.

THE MINERAL PRODUCTION of Indiana was valued at over $80,000,000 in 1913.

Spelter—Manufacture and Properties

By GEORGE C. STONE

*The chemical properties of zinc are unique and render its extraction from an ore impossible by the methods used for the other common metals. The temperature at which oxide of zinc is reduced by carbon is considerably higher than the volatilizing point of the metal, so that it is always produced as a vapor. In order to obtain the metal in a commercially useful form it must be condensed at a temperature above its melting point, because if suddenly cooled to a solid it condenses as a powder, which oxidizes very readily and cannot be remelted and cast to form a solid. In ordinary metallurgical practice the oxide of a metal is heated with carbon or in an atmosphere of CO, either of which reduces the oxide to metal under the conditions which are maintained in the furnace. The reaction is

$$2RO + C = 2R + CO_2$$

or

$$RO + CO = R + CO_2$$

The furnace atmosphere is essentially a mixture of nitrogen, carbon dioxide, and carbon monoxide, and for all metals but zinc the presence of a considerable amount of carbon dioxide is not harmful. For zinc the case is different, as the presence of even a fraction of a per cent of carbon dioxide causes the action to reverse, and we have

$$Zn + CO_2 = ZNO + CO$$

It is therefore necessary always to have an excess of carbon present in order to produce metallic zinc, and the reaction is either

$$ZnO + C = Zn + CO$$

or

$$ZnO + CO + C = Zn + 2CO$$

These reactions were not known, and zinc as a metal by itself was not known, until early in the nineteenth century. Zinc as a constituent of brass was known for centuries before this. The old method of making brass was to heat the zinc ore with copper and charcoal. The zinc was reduced by the carbon and immediately alloyed with the copper and was thereby prevented from volatilizing completely, as it would if the copper were not present. The percentage of zinc in the resulting brass was naturally very uncertain and the quality of the product varied greatly. I have, myself, made brass in this way, maintaining as uniform conditions as possible, and the brass from the different runs contained from 8 to 25% of zinc.

There are two main classes of ores, the sulphides, blende, and the oxidized ores, carbonates, and silicates. The sulphides must be roasted to oxides before smelting. The oxidized ores require no preliminary treatment. Blende is the most abundant ore of zinc and is mined in Virginia, Kentucky, Tennessee, Missouri, Wisconsin, and all of the Rocky Mountain states. It is usually associated with galena (sulphide of lead) and pyrite (sulphide of iron), and therefore usually requires mechanical concentration to separate it from these minerals.

The oxidized ores are found in the same localities as blende, and also in New Jersey, which contains the largest deposits of oxidized zinc ores in the world at Franklin Furnace. In most cases oxidized ores are associated with lead, which is removed as completely as possible by mechanical concentration.

All zinc ores contain iron, usually in considerable quantity. Most of them also contain cadmium in much smaller quantity. The effect of these impurities will be discussed later. The peculiar chemical properties of zinc limit the possible types of furnace to be employed, and, as a matter of fact, all of the successful zinc furnaces have been of the same general type.

The Spelter Furnace

A spelter furnace consists of a chamber with a solid roof and solid walls on three sides. The fourth side is an open frame of firebrick. Retorts closed at one end are placed in this chamber, resting on the open front frame and on projections from the opposite wall. The open ends of the retorts project slightly from the furnace, and the space around them is luted tightly with clay or a mixture of clay and coal. The furnaces are heated either by direct fires or by gas. When the furnace is sufficiently hot the charge, consisting of a mixture of crushed ore and coal, is thrown into the retorts with considerable force so as to pack it tightly. A small rod is then pushed through the charge near the top of the retort to make a vent for the gases formed. This operation is called 'spiesing,' in the East.

The condensers, short clay cones, are then fitted into the open ends of the retorts and luted with coal. The large ends of the condensers are placed in the retorts and the outer ends are supported on pieces of brick resting on the shelves in front of the furnace, or on movable iron rests called grasshoppers. The mouths of the condensers are partly stopped with coal to prevent the entrance of air and loss of heat. The heat in the furnace is gradually increased and the condensers watched to make sure they do not get stopped up, which would result in an explosion of the gas confined in the retort. The gas at the end of the condenser is lighted and burns at first with a clear red, yellow, or blue flame. In a short time this becomes smoky and tinged with green, showing that the zinc is beginning to come off.

In about six or eight hours enough zinc has been distilled to make it necessary to draw it. This is done by scraping the liquid zinc and oxide in each condenser

*Read before the American Institute of Metals and revised and extended by the author.

into a ladle held below it. When the ladle is full the oxide is skimmed off and the metal poured into molds. The operation of drawing requires considerable skill, as all of the material in the condenser should be removed quickly and none of the charge from the retort dragged with it. It is also important that none of the metal in the condenser should be pushed back into the retort, as, if it is, it will immediately be volatilized, will burn, and be lost.

As soon as the condensers are drawn a helper again stops their mouths with coal. The heat is gradually increased, and in another six hours or so a second draw is made. After the second draw the heat is increased as much as possible and maintained to the end of the charge. When the charge is worked off a third draw is made, the condensers being cleaned as thoroughly as possible. The condensers are then taken out and the material in the retorts removed either by scrapers or by blowing out with steam or water. The latter operation sounds rather barbarous, but is not as bad as it sounds. It is performed by pushing a pipe through the material in the retort to the back end and turning on steam or water for an instant. If water is used it is immediately converted into steam and acts like an explosion, blowing the material out of the retort. When steam is used, it is usually very wet, owing to condensation in the long pipes necessary.

Any used up retorts are then removed and replaced by new ones, which are brought red-hot from the kilns, which should be close to the furnaces. The furnace is then recharged and the operation goes on as before. It requires twenty-four hours to work off a charge. The ladle skimmings, condenser scrapings, chips from old retorts, and any metal spilled, are carefully collected and added to the next charge.

The success of the operation depends on the proper mixing and proportioning of the charge, the regulation of the heat, and the care and skill of the workmen.

Organization of the Crew

Up to 20 years ago the furnaces were very small and were all fired directly with coal. A furnace crew then consisted of a charger and a long-shift man, both of whom worked 24 hours, and a short-shift man who worked 12 hours. They wheeled and mixed the charge, fired and worked the furnace, drew the metal, replaced retorts, and took the metal made to the storehouse. The charger was responsible for the firing of the furnace, and the success or failure of the work depended almost entirely on him. It was never easy to get sufficiently intelligent, careful, and skillful men who were willing to work 24-hour shifts, and it became increasingly difficult to do so as other lines of employment opened. The endeavors of the managers have therefore been to design furnaces and plants that do not depend so entirely on the skill of the workmen. In this they have been largely successful. The charges are now usually mixed by machinery, concrete mixers being frequently used. The furnaces are fired by gas, giving easy regulation. The spelter was formerly drawn off in hand-ladles holding about 40 lb. each. These had to be moved by hand from retort to retort, lifted up and down, and carried to the molds. While doing this work the men had to stand close to the furnace with no protection from the heat. At the present time much larger ladles, holding from 200 to 500 lb. are used. They are carried on cranes or cars provided with shields to protect the men from the heat of the furnace. When the ladle is full the car is run to the molds and the metal poured, the ladle being still carried on the crane, by which its height can be adjusted for convenient pouring.

Working Conditions

The ventilation of many of the old spelter furnace buildings was very defective and they were frequently full of smoke and gas. In strong winds this was particularly troublesome, as it was necessary to close all openings on the windward side of the buildings because drafts interfere with the working of a furnace. At the present time the furnaces are usually built with very large hoods and clear openings over them so that the ventilation of the rooms is practically perfect. At some works an air pipe is run near the roof and parallel to the front of the furnace with open branches pointing toward the floor at a point about two feet back of the position of the men when working at the furnace. By moving back one step the men can get the cool draft and do not have to stay in it long enough to get chilled. This has proved of great advantage in hot weather. The general health of spelter men is excellent and no occupational diseases due to zinc are known. In a few cases where ores high in lead are worked authentic cases of lead-poisoning have occurred. The so-called 'spelter shakes' are unknown in zinc works, proving that this trouble is certainly due to something other than zinc.

The work is so arranged that no men work more than twelve hours, and most of them only about six. The largest number are required when cleaning out and charging. As soon as this is completed, all but the metal drawers are free to go home. It is still hard, hot, dirty work, and the hours are inconvenient, as the cleaning out usually starts at 4 or 5 a.m. The men prefer this early start, as it is the coolest hour in summer.

There are several kinds of furnaces in use—the old direct-fired furnace with the fireplace below the retorts has practically disappeared in this country. None are now in operation, and those still in existence will probably never be started up again. The simplest of the gas furnaces is the Hegeler, invented by Edward C. Hegeler, one of the pioneers in zinc smelting in this country and one who has probably done more than anyone else to improve the practice. The Hegeler furnaces are very large, some containing as many as 1080 retorts. The gas is all admitted at one end, the producer being placed close to the furnace so as to utilize as much as possible of the sensible heat. The air is admitted at different points lengthwise of the furnace so as to burn the gas gradually.

The furnaces used in the natural gas field are similar except that both gas and air are taken in at intervals along the front. This type of furnace is cheap to build and easy to operate, but is not economical in fuel. To Mr. Hegeler this made no difference, as he had very cheap fuel and means for utilizing all of the waste heat.

Various modifications of the Siemens furnace are largely used. In these the retorts are faced two ways, the butts of all resting on projections from the centre wall, which does not come quite up to the roof. There are four regenerators under the furnace, and the gas and air coming from two of these enter ports under the lowest row on one side and pass over the centre wall through ports below the retorts on the opposite side to the other pair of regenerators. At regular intervals, usually of about half an hour, the gas and air are reversed in direction. In this way the retorts are kept at a fairly uniform temperature. This type of furnace is very economical in fuel, but requires considerable care and judgment to get and maintain a uniform distribution of heat. It is impossible to keep the regenerators clean, and they gradually lose their efficiency.

The Convers de Saulles furnaces are used by only one company. In these the gas is taken hot from the producers and the air is heated in continuous regenerators. Both air and gas enter both sides of the furnace under the lowest retorts and pass out through the hollow back wall. As the air alone is regenerated, this furnace is not as economical as the Siemens, but is much easier to operate. The regenerators are built with straight passes that can be kept clean so that the efficiency of the furnace can be maintained until the brickwork of the chamber gives way.

In Europe several other furnaces have been used with considerable success, but none of them have proved satisfactory when tried in this country.

A very important accessory operation is the manufacture of retorts. Formerly they were made entirely by hand, which was slow and required a skilled potter. At the present time they are made in tile machines, or more often in hydraulic presses. The latter makes much denser retorts than either of the other processes, and they can be made with much thinner walls and are therefore easier to heat. After pressing, the retorts are placed in drying rooms where they are kept for three months or longer. Each morning the pottery man finds out from the furnace men how many retorts will be required the next day, and places the proper number in the kilns, where they are burned with coal or gas for about 18 hours. The kilns are close to the spelter furnaces and the retorts are transferred while red hot.

Impurities in Spelter

The commonest impurities in spelter are lead, iron, and cadmium. Arsenic is also common, but very little attention is paid to it. All of these impurities are derived from the ore and will be found in the spelter if they occur in the ore. In other words, it is impossible to make pure spelter from impure ore. The extent to which the different impurities in the ore go to the spelter varies considerably.

When lead is present in the ore in very small proportion (about one of lead to a thousand of zinc), practically all of it will be found in the spelter. As the proportion of lead to zinc in the ore increases, the proportion of the total lead that goes to the spelter decreases. It is difficult to make a spelter containing much over 2% of lead, no matter how much the ore contains. Lead and zinc make fairly homogeneous alloys up to about 1% of lead. When more is present it segregates badly.

Iron behaves differently, and the amount of it found in the spelter depends mainly upon the way the smelting is conducted, and not on the amount in the ore. It is possible to make spelter from ore that contains 10 or 12% as free from iron as from ore that contains 0.1 to 0.2%. The two causes that mainly contribute to the presence of iron in the spelter are careless drawing, by which part of the charge is drawn into the condensers, and poor scrapers which wear off and introduce particles of iron.

Cadmium is much more volatile than zinc and a good deal of that contained in the ore escapes condensation, so that the spelter never contains as much cadmium as the composition of the ore would lead one to expect. The behavior of arsenic has not been much studied, but it is known that it is found in the spelter whenever it occurs in the ore. Aluminum and tin are never found in virgin spelter, that is, spelter made from ore. Tin never occurs with zinc, and aluminum is not reduced under the conditions occurring in a spelter furnace.

Commercial spelter is divided into four grades, defined as follows by the Amer. Soc. for Testing Materials:

(*a*) *High-grade.*—Shall not contain over 0.07% lead, 0.03% iron, 0.05% cadmium, and it shall be free from aluminum. The sum of the lead, iron, and cadmium shall not exceed 0.10 per cent.

(*b*) *Intermediate.*—Shall not contain over 0.20% lead, 0.03% iron, 0.50% cadmium, and it shall be free from aluminum. The sum of lead, iron, and cadmium shall not exceed 0.50 per cent.

(*c*) *Brass special.*—Shall not contain over 0.75% lead, 0.04% iron, 0.75% cadmium, and it shall be free from aluminum. The sum of the lead, iron, and cadmium shall not exceed 1.2 per cent.

(*d*) *Prime Western.*—Shall not contain over 1.50% lead and 0.08% iron.

The following table gives the analyses of typical samples of the various grades:

	Pb	Fe	Cd
High-grade	0.010	0.026	0.04
" "	0.041	0.014	None
" "	0.035	0.014	"
Intermediate	0.095	0.009	None
"	0.190	0.017	"
"	0.123	0.011	0.12
Brass special	0.343	0.026	None
" "	0.474	0.013	"
" "	0.680	0.010	0.274
Prime Western	0.870	0.062	0.023
" "	0.644	0.013	0.090
" "	1.270	0.011	0.079

Strength of Spelter

Spelter is a highly crystalline metal and its tensile and transverse strength depend entirely on the size of the crystals. The tensile strength varies from about 2 tons per square inch with coarsely crystalline specimens, to 7 tons with very fine grained ones. The composition does not appear to influence the strength greatly. The transverse strength also varies with the crystallization, being greater the finer the grain. The modulus of rupture varies from 4 to 11 tons per square inch with deflections of from 0.09 to 0.44 in. on a span of 12 in. There is no definite relation between the modulus of rupture and deflection. The purer the spelter the higher the deflection it will stand without cracking.

The compression test pieces were cylinders 1 inch in diameter and 2.6 in. long. The load necessary to compress these at 10 and 20% was determined:

Names.	10%	20%
High-Grade	16,500	23,095
Intermediate	16,065	23,095
Brass Special	18,310	26,000
Prime Western	20,570	28,620

The resistance to compression increases with increase of impurities. The effect of the different impurities varies greatly. Lead has but little influence. Iron has comparatively little influence. Cadmium increases the resistance to compression very greatly. A cadmium-free Brass Special spelter required 17,190 lb. to compress it 10%, while a Prime Western spelter with 0.32% cadmium and about the same quantities of lead and iron as the other required 27,340 lb. In another case a cadmium-free metal required 16,500 lb. for 10% compression, while the same metal to which 0.2% of cadmium had been added required 26,870 lb. For 20% compression the cadmium-free required 24,000 lb. and the metal with 0.2% cadmium 37,000 pounds.

Effect of Impurities

Lead.—Lead in moderate quantity tends to make spelter softer in rolling; in galvanizing it has a tendency to weaken the coating and make it more liable to peel when the coated metal is bent. Present in quantities of about 0.7% it tends to produce bad cracking in spelter castings. In brass it tends to make the alloy more brittle and liable to crack.

Iron.—Iron hardens spelter and makes it more brittle. This effect seems to follow through all of its uses. In galvanizing, excessive iron also tends to make more dross, the iron being present in the form of a solid alloy, gradually settles to the bottom of the pot; though this effect is slight, as much more iron is added to the bath by the containing vessel and the material being galvanized than can possibly be present in the spelter.

Cadmium.—The effect of cadmium is to harden spelter greatly and make it more brittle. In galvanizing, this is very important, as the brittleness due to the cadmium causes the coating to peel off. This is of particular importance in telephone and telegraph wires which are sharply bent in making splices. If the zinc contains appreciable quantities of cadmium the coating peels off at these points and the life of the line is much shortened. Cadmium has a strong tendency to make castings crack. In brass, cadmium tends to act like lead and is also said to make the metal more sensitive to heat treatment. Luckily for the brass makers a large part of the cadmium in the spelter they use is volatilized and lost, so that the amount in the resulting brass is rarely large enough to cause much trouble.

Arsenic.—In the ordinary uses of spelter, arsenic in the quantity in which it occurs does not appear to have much effect. When used for generating hydrogen to be used in lead burning, it does, however, have a very important influence, making it impossible to burn a strong seam.

In general, the purest spelter gives the best results, and very pure spelter can only be made from pure ores. There are several refining processes which reduce the amounts of some of the impurities and have little effect on others. In Europe it is customary to remelt all of the lower grade spelter corresponding to our Prime Western. This is done in large reverberatory furnaces holding as much as 15 or 20 tons of spelter, which is heated to a temperature just sufficient to keep the metal liquid. A considerable part of the lead and some of the iron settles to the bottom of the furnace, and the purer zinc is ladled from the top and cast for sale. The lead is reduced to about 1% and the iron to about 0.03%. Cadmium is very little affected, as it dissolves in the zinc in amount up to 1% and, therefore, cannot be separated by liquation. The main advantage is not so much in the reduction of the amount of impurities as in the production of a more uniform grade of metal.

In this country the so-called refining is usually the treatment of scrap and galvanizers' refuse in the production of what the government calls 'secondary' zinc. The product made is of uncertain quality and usually contains impurities, notably tin and aluminum, not found in spelter made direct from ore. While some of this material shows a fairly good chemical composition, it is usually hard and brittle, due to excessive cadmium, and will not produce the results for galvanizing, alloys, or castings that can be obtained from good virgin spelter.

Castings

Spelter is largely used for making ornamental castings, mainly what are known as 'slush' castings—that is, those in which the metal in the mold is poured back into the ladle as soon as a thin layer next the mold has set. These castings are made as thin and light as possible to economize metal, and a material that will not give light castings is therefore unsuitable. The castings must be sound, not merely for strength, but because they are all ornamental in character. A single crack (or even two or three), if not large enough to impair seriously the strength, is not fatal, as such cracks can be soldered and finished so as not to show. The most objectionable cracks are the very small ones that are not visible, because the plating solution gets into them and does not show until

the work is finished, when it comes to the surface producing stains that ruin it. The molds are usually made of bronze, and many of the shapes are such as to cause excessive strains. The castings are polished and plated or otherwise finished. It has long been known that such castings could only be made from pure metal, but I do not know of the effect of the different impurities having been studied.

Our first experiments were made with a very simple and easy casting, and indicated that iron up to 0.07% had no bad effect, and that both lead and cadmium greatly increased the tendency to crack when present in considerable quantity. We next made slush castings of a fairly difficult shape, starting with the pure, high-grade spelter, to determine the necessary conditions. We then made a series of alloys by adding lead directly to zinc at a temperature of 700°C. (1292°F.), the metal being kept well covered with charcoal and stirred for ten minutes with a rod of fused silica. The cadmium alloys were made by melting together pure spelter and an alloy containing 1% of cadmium. Each of the lead alloys was used as the base of a lead-cadmium series, the necessary amount of the 1% cadmium alloy being added.

The alloys were melted in 80-lb. lots in No. 45 Dixon graphite crucible, the alloy containing the least amount of impurities in each series, being made first, and the crucible carefully scraped and cleaned with sandpaper before being used again. The following method was adopted as the result of the experiments on pure spelter. The charge was melted, stirred, and brought to approximately the desired temperature, 435 to 460°C. (815 to 860°F.), and three castings were poured to heat the mold. These castings were set aside and melted later if it was necessary to cool the bath. The temperature of the bath was taken before each casting with a platinum-platinum iridium couple protected by a fused quartz tube. While each reading was being taken, the bath was stirred slowly and the galvanometer needle allowed to become stationary. The inside of the mold and ladle were kept well covered with soot from turpentine smoke. Between casts the ladle was kept uniformly warm by placing it directly over the crucible.

The results of these experiments are given in the accompanying table.

EFFECT OF IMPURITIES ON SLUSH CASTINGS

Desired composition. Pb	Cd	Analysis. Pb	Cd	Casting temperature. C.°	F.°	Total number of castings	Number of perfect castings	Number perfect weighing less than 850 gm. The effect of lead alone when present in amount exceeding 0.1% is to cause cracking, and any attempt to reduce this by lowering the casting temperature results in the production of castings of excessive weight. Lead does not alloy with zinc at the casting temperature, but separates as small drops or films between the crystals. These form lines of weakness which cause cracks along the irregular lines where crystals meet. When the cracking is due to lead, there is usually only one large crack extending about half way around the casting and opening about one-thirty-second of an inch and quite frequently to one-sixteenth inch.

Cadmium forms hard and brittle solid solutions with zinc at all temperatures, and we only succeeded in getting 2 satisfactory castings out of 160, from metal containing 0.1% or over of cadmium. When the amount of cadmium does not exceed 0.2% the cracks are similar in appearance to those due to lead. With larger quantities of cadmium the cracking is of a much more objectionable form, as there are usually a large number of cracks scattered over the surface, some of which are so small that they are difficult to detect. As would be expected for theoretical reasons, cadmium very decidedly lowers the melting point, and we were able to pour castings from high cadmium alloys at a temperature of 10°C. (18°F.) below that at which pure spelter would flow.

The effect of the presence of both lead and cadmium about equals the cumulative effect of the two if present separately. Alloys containing large amounts of lead (0.4 to 0.5%) with 0.1% cadmium, however, will sometimes give sound castings, but only when their weight is excessive. It is possible that this is due to the soft lead segregated in the joints between the crystals acting as a lubricator and allowing them to slip enough to relieve the strain without cracking.

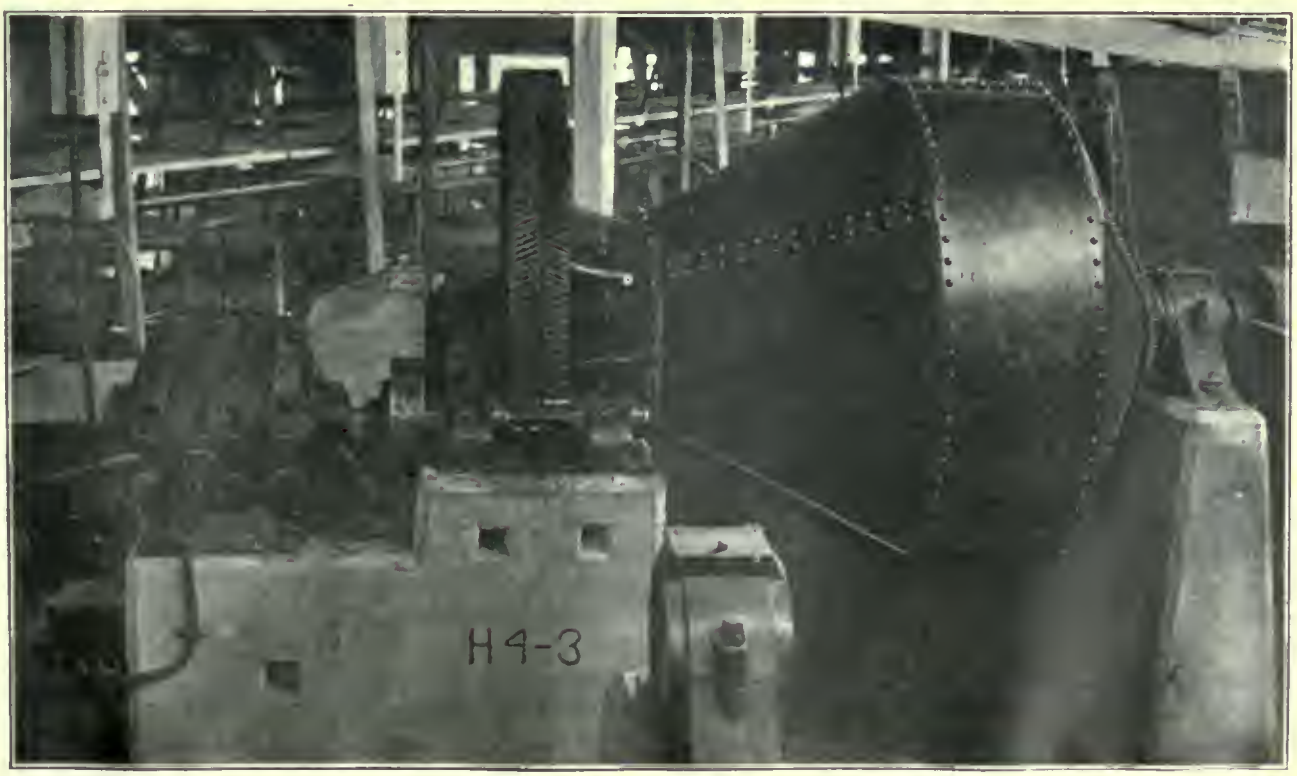
Conclusions

1. Both lead and cadmium are injurious in spelter to be used for slush castings.
2. The lead should not exceed 0.1 per cent.
3. The spelter should be free from cadmium.
4. It is possible to obtain sound castings from less pure metal, but can only be accomplished by making them excessively heavy.

In conclusion I wish to express my indebtedness to Henry E. Morse, who has carried out all of the experiments on castings, making the alloys, the castings, and doing the metallographic work in connection with them in the most satisfactory manner.

Use of Herringbone Gears to Drive Hardinge Mills

'Steam Stamps from the Gold Miner's Point of View' was discussed by Algernon Del Mar in the *Mining and Scientific Press* of October 3, 1914. The regrinding mill of the Calumet & Hecla company was discussed, mainly in connection with the Hardinge mills. Mr. Del Mar further states that probably he did not make the point clear that the saving of from 10 to 15% in power for driving the Hardinge mills was from the use of herringbone gears direct from the motor shaft to the cone, instead of the usual countershaft drive by belt or silent chain. The accompanying halftone shows a mill driven by motor with Wuest herringbone gears. If this saving can be made on a Hardinge, the natural question is why this style of drive gears has not been used for driving a cylindrical mill. The usual belt drive is not effective when the reduction in size of pulleys is greater than 6 to 1, while the herringbone gear is effective to a reduction of 20 to 1, or greater. By this means the loss



AN 8-FT. HARDINGE MILL WITH WUEST HERRINGBONE GEAR DRIVEN BY A 50-HP. WESTINGHOUSE MOTOR.

of power due to slipping belts, and the friction in at least two bearings, is dispensed with, irrespective of the gain in floor space, and the advantage of having the motor and tube-mill on one foundation. In a recent description of one of the large mills, the statement was made that the belt drive on the tube-mill was entirely satisfactory, which does not mean that it was satisfactory as to the power consumption, but that it gave no trouble in turning the mill. The tests made in the Lake Superior mills included belt-driven and ordinary straight gear-driven machines. The herringbone gear proved superior to all others.

Stabilization of the Copper Market

By C. S. BURTON

The abnormal conditions prevailing in the copper market since the outbreak of the war in Europe have been much like those in cotton. Like the chief product of the South, copper is turned out largely for foreign consumption, perhaps too largely so. In a larger sense, the foreign demand for copper has wrought a market condition that is bad from the point of conservation of our country's natural resources, particularly in such a source of wealth as copper, which cannot be replaced. The past decade and a half has seen copper production undergo a tremendous transformation, almost wholly by reason of advances in metallurgy. The primary result of such forward steps in the recovery of metal from low-grade orebodies has been the investment of huge sums in reduction works and the formation of great organizations, predicated upon the winning from the earth an amount of copper possible only by the handling of immense tonnages at a minimum of cost.

Necessity for Continued Production

The unfortunate feature of such development lies wholly in the fact that such huge plants must be kept going and the organizations must be held together. In other words, shut-downs and curtailments, common enough in mining ventures of the ordinary type are quite out of the question with the low-grade milling coppers. The advantages gained by the immense production are to be considered, to be sure, but the deplorable feature of the situation is that the lion's share of the profit, aside from that to the mining companies themselves, has been reaped not by our own consumers, but by foreigners.

The copper metal market has always been an attractive field for the man with both daring and money; it has been the scene of more than one big attempt to control the world's supply, and up to a few years ago, the price of copper was one of the most uncertain of earthly things. When it became plain that the huge output of copper could not be maintained without some stability of market, strong hands took control and by tacit understanding have since prevented the accumulation of any threatening surplus. Notwithstanding such efforts, however, there has existed and still exists an economic weakness in the copper situation in that the huge units of production, each seeking to make the most of its own opportunity by carrying a peak load all the time, cutting down its interest charges, and extracting and marketing its product in the least possible time, have kept the world's demand supplied constantly to a point just short of saturation. This condition has redounded to the advantage of the foreign buyer much more than it has to the domestic consumer. Put another way: the home manufacturer has come in on rising prices for metal, the foreign buyer when the market was declining.

There have recently been unprecedented conditions in the market for raw cotton. Prices were such that the spinner could afford to stock up for months to come, and yet the great cash crop of the South has been begging for buyers. The spinner was without a 'contract' or 'future' market in which he could hedge or insure himself against fluctuation, consequently to stock up with cotton meant that he must buy outright and warehouse his purchase, bearing the entire weight of the outlay and without means of limiting or fending against possible loss. Anyone familiar with the course of business in commodities must realize how necessary it is for the cotton spinner to have a contract market in which he can hedge against whatever position he finds it necessary to take.

No Machinery for Copper Trading

In copper, there exists no such machinery, at least not on this side of the water. There is nothing to which the manufacturer can turn to protect himself, there is nothing to take up any lost motion. Domestic consumers have therefore adopted a hand-to-mouth attitude, and have evidently adopted it permanently; on the theory that it will be possible at all times to buy copper, and, in the long run it will be better business to buy, as their needs dictate, and make the price of their product accordingly, than to attempt to pick out any soft spots in the metal market, when they have to take the entire gamble upon their own shoulders. It is by no means for the domestic consumer alone, that an open speculative market in copper metal would prove attractive. As matters now stand, there is no method by which the general public can participate in any movement in copper. Purchases by the outside public would be a great stabilizing factor, when the metal threatens to reach or break through its cost of production, just as sales would act contrariwise when a threatened copper famine begins to drive prices abnormally high.

Had there been some such machinery in action during the two and a half years preceding the outbreak of hos-

tilities, it is safe to say that the copper which went abroad during that period would have cost the English and German armament makers materially more than it did. Following the panic year of 1907, there was a period during which accumulated stocks of metal assumed threatening proportions and domestic consumers felt justified in the stand that there was no necessity for buying ahead so long as the producers had to carry the burden in any event. It was not until 1911 that the producers managed to put into effect a policy of curtailment of production that was effective enough to bring our manufacturers into the field on a rising market. The year 1912 saw price conditions better than they had been in five years, and many students of the situation voiced the opinion that there would be no return to the days of cheap copper. In view of the increased shipments abroad this position was probably justified. In 1912 exports accounted for 47.5% of our production; in 1913 we sent overseas 53.1% of our output and during the first half of 1914 and up to the time when the Copper Producers' Association ceased to give out the regular monthly figures, the percentage was still increasing, averaging for the six months 59.7% of the total consumption. The weakness of the situation lies in the fact that these record-breaking shipments abroad were made on a falling market. In January of 1914, copper was around 14½c. per pound; in spite of the foreign demand the price had eased to less than 14c. in July. If there were open trading in copper, this demand for overseas trade would have had a clear meaning to some market followers, and whether it would have foretold the outbreak of the war or not, it would have told of conditions that would have justified speculative buying, such as would have marked the price up. Even today, when copper exports are increasing and millions of pounds are known to have been destroyed, there is no way for the public to participate in the legitimate movement of one of the greatest of our natural resources, a resource which bids fair to be exhausted all too soon.

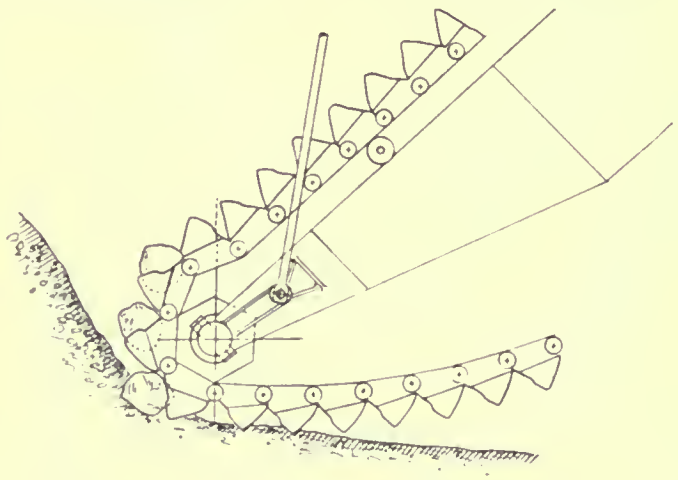
The situation in this particular regard is not unlike that of the German potash deposits, which were promptly protected by government action when it appeared that in order to keep the works going it would be necessary to make a low price and increase shipments to the United States. The ownership of copper properties is too diverse, and natural competition too strong, to permit of imagining any such emergency measure, but an open market in the metal would cause some study of copper costs, some knowledge of the actual average cost of a pound of copper would become prevalent, and a new kind of home consumption might intervene to prevent the cheapest of our metal from going abroad, and instead to force the payment of a better price; not only would the public have a chance to participate in profits in a new way in addition to holding shares in mines, to which it is at present limited, but the domestic manufacturer would have a much enlarged opportunity to become a market factor and could buy with much greater advantage, both for himself and the producer.

Handling Boulders at Andrada

By L. C. de La MARLIERE

The handling of boulders in alluvial deposits has always been considered by experts one of the most difficult obstacles in dredging, and many placers have been condemned because of the great quantity of big boulders found thereon. When the boulder is too big to be lifted by the buckets, according to size of the latter, it is usual to pass over it, or to push it in deep water. A clever winchman can accomplish this, but when it is necessary too often, dredging is not a success because of loss of time. For good dredging, all the boulders contained in the ground should be lifted, especially when they are near the bedrock, where the most gold generally is found.

Let us consider the best way in which boulders can be lifted by the buckets and be cast out. Suppose the composition of the ground to be dredged has been well tested by prospecting shafts. Drilling with Keystone or similar machines, while quite adequate in certain ground, is not accurate enough in deposits containing big stones and boulders. The size of the buckets should be decided according to the average size of the boulders. If these are correctly designed, a close-connected chain will easily lift boulders and without damage to the buckets. This statement must be insisted upon, as the partisans of the open-connected chain have long contended that the close-connected bucket-line would be a failure in ground containing many boulders. Their argument is based on the fact that if a big boulder be caught between two buckets (as they open while going around the under part of the lower tumbler) these buckets cannot close again as they reach the upper part without the bottom of the superior bucket being broken by the boulder being squeezed between this and the following one.



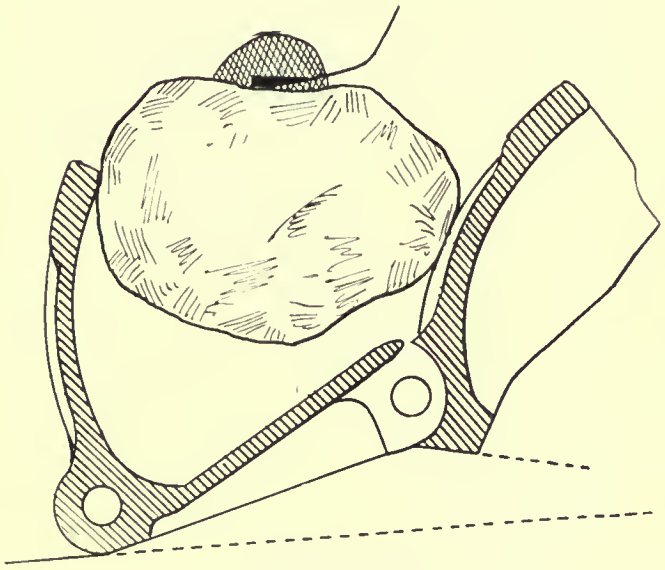
BUCKET-LINE PICKING UP BOULDERS.

Contrary to what has been claimed, no damage can be done to the buckets if they are strongly built. The buckets take their place again after having gone around the lower tumbler. The boulder finds its place sometimes after having been crushed by the buckets. The worst that may happen is that the two buckets between

which the boulder is caught may open in going upward to let the boulder take its place. Furthermore the experience proves that the close-connected line is a help in that the buckets catch the boulders, acting on them exactly as a nut cracker.

In 4⅔ months, from February 10, 1914, to the end of June of the same year, the Alpha dredge of the Andrada Mines, Ltd., a close-connected 7½-cu. ft. boat constructed by the Bucyrus company, and in the Portuguese territory of the Mozambique country near the Rhodesian border, has treated in a ground full of boulders, and of clay, 547,500 cu. yd. and has picked up 4400 boulders weighing on an average of over a ton each, without any serious damage to the buckets.

This argument of the partisans of the open-connected



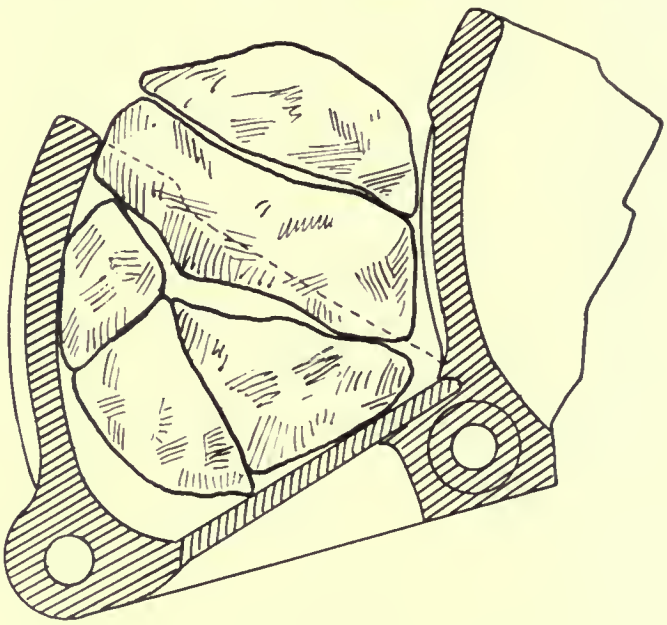
BEFORE BLASTING.

bucket, as well as all others, has therefore no real force in the actual state of perfection of the close-connected bucket-line.

Elimination of boulders from the buckets is the most delicate part of the work. The method in general use is to stop the bucket chain, and, after tying the boulder with slings, to raise it with chain blocks suspended to a moving crane, and to set it on the deck. When the boulder is very big and is squeezed in between two buckets, this operation requires at the least 10 minutes. By this method the Alpha dredge has pulled up over 200 boulders weighing an average of one ton, and the time lost has averaged just about 10 minutes per boulder. In February, however, the number of boulders found became so large that the removing of them by crane operated at first by hand and later by winch, caused such loss of time that the actual dredging fell to about 50% of the capacity of the boat. It was then that we decided to try to crack the boulders in the buckets by blasting them and to eliminate them in pieces through the screen and stacker. The method proved very successful.

A dynamite cartridge is placed on the boulder, covered with clay, and fired. The boulder is not broken in small pieces, many of which in flying might injure the dredge, but is only cracked and settled in the buckets. The action of the dynamite on the boulder is very effective, as the boulder is caught at its two extremities and not held in the middle. The force of the dynamite acts on the least resisting part, which is the middle of the boulder, and does not damage the buckets. There is no doubt that the success of this blasting is greatly due to the close-connected bucket-line and that it would not be so effective on a boulder simply laid on an open-connected line.

During March 1914 the Alpha dredge picked up 1510 boulders, fired 1544 dynamite cartridges, and lost by this method about 1800 minutes, say 60 per day or 1.2



AFTER BLASTING.

minutes per boulder. During this month the same dredge treated 131,000 cu. yd. in ground averaging 15 ft. deep. In four months the chain of 62 buckets has withstood 4600 blastings (nearly 72 blasts per bucket), and only 5 buckets were pierced in the hood. The holes, in these cases about 5 in. diameter only, were easily patched and did not interfere with the working of the line. Only 24 rivets were loosened; this, without any inconvenience to the buckets.

No accident happened to the framing, housing, or machinery of the dredge. The only drawback in blasting is that it is impossible to keep in good order the electric lamps lighting the bow of the dredge. An acetylene light should therefore be substituted for the electric light and equipped with very strong and well protected drums, or the bow of the dredge could be protected by covering the buckets, where the blasting is going on, with an iron cone easy to raise and to lower with a pulley from the winch room. The experiment of blasting boulders in buckets, which we believe has never been tried before, is very conclusive and can be undertaken without danger, providing that care be taken as to the quantity of dynamite and the best place to use it and that the work be done on buckets of sufficient strength.

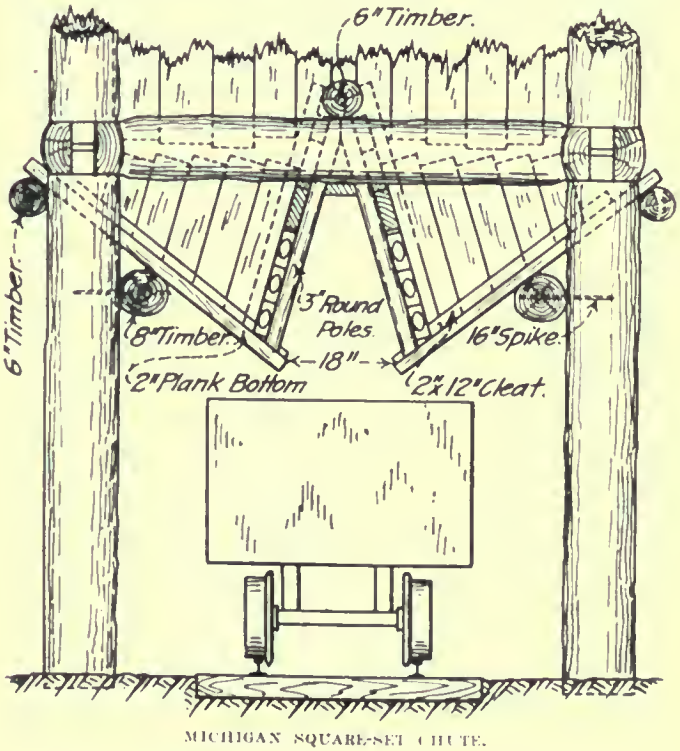
Efficiency in Michigan Copper Mines

Unlike the Lake Superior iron mines, where 'efficiency engineering' has received only fitful encouragement, the Lake Superior copper mines have given it careful and systematic attention for several years. In fact, the zeal of the copper companies for efficiency engineering became possibly a little too absorbing; for it is no secret that it was one of the indirect reasons for the long and costly Lake Superior strike. Two or three years ago, it was rumored around Lake Superior that the new efficiency campaign in progress with the Calumet & Hecla companies would save them half a million dollars or more per year. The cost of driving had been reduced 30 to 40% and the cost of stoping 10 to 20%. At the same time, apart from the attitude of the miners who did not take kindly to the efficiency methods, the thorough tabulations of rock drilling and mining methods brought to light by the campaign were interesting. An outsider would be surprised at the detail with which the art of rock drilling was studied. For instance, the operation of cranking back a rock-drill on its feed-screw, performed three or four times for every hole drilled, was found to take a certain number of seconds under ordinary conditions. But when the crank handle was fitted with an iron ring or flywheel (like that on a large ice-cream freezer), 8 or 10 inches in diameter, it was found that cranking back took several seconds less each time. With such a flywheel, given a few swift turns, a well greased rock-drill would nearly screw itself back. In a small mine such a detail would, of course, not be worth bothering about, but with several thousand men of the Calumet & Hecla companies, it was considered worth while. In the experiments using compressed air of different pressures for running rock-drills, it did not always make a drill operate faster or hit harder to increase the air pressure. For instance, one drill of certain make and with a certain kind of valve, drilled faster with air at 70 lb. pressure than with air at 85 lb. Other rock-drills required the high pressures for best working. One drill could not stand too much air at once, and worked best with the air inlet cut down to ¼ in. Water in the compressed air affected some rock-drill valves badly, and made them freeze; another type rarely froze. Rock-drills with a 'short-stroking' attachment were desired, not only for convenience in 'fitchered' holes, but for using drill-steels slightly too long for the full stroke, as often happens in changing steel, and for general desirability in starting holes. The attention given to setting up a column with its swinging arm and saddle, was also very close and several small mechanical appliances were invented to hasten that part of the miner's work. Another feature adopted by some companies is the use of ⅞-in. drill steel in place of 1⅛-in., which reduces the area of the drill holes so that with less rock to cut, the cutting goes faster, requiring, however, higher per cent dynamite in narrower sticks. On the South Range, where the Copper Range Con. mines use the 'dry-wall' method of stoping (the lodes are too flat for it at Calumet), tailing from the stamp-mill is brought back in the ore cars and piped and blown by compressed air into the stopes for standing on to reach the back, in this way eking out the waste rock ordinarily used to stand on as a result of the sorting underground. It was formerly necessary to tap old stopes for additional waste or to blast it from the walls, which methods were expensive, especially the latter.

In 1909, when two-man drills were in use, the average driving per man per shift was 0.7 ft. for the Superior mine (as well as approximately for the entire copper country). In 1911, when the Calumet & Hecla had introduced one-man drills and efficiency methods in its Superior mine, where these innovations were first given trial, that mine raised this figure to 1.2 ft. per man per shift, and a little later to 1.5. Since then all the Calumet & Hecla companies have introduced the methods tried out in the Superior, as have most of the other operators also, and nearly as startling gains in efficiency have been made as was the case in the Superior.

Square-Set Ore Chute

The accompanying sketch is that of an underground ore chute on the Mesabi range. This chute has been widely adopted for the loading of cars underground and is proving most satisfactory largely because of the simplicity and ruggedness of construction. The ore is fine, soft, and sometimes wet, and is discharged from the chute



MICHIGAN SQUARE-SET CHUTE.

through the gates made of three round poles, as shown in the sketch. The timbering is of the 'round square-set' type and the construction as shown in the sketch. The chute was developed and has been adopted as standard in the mines of the United States Steel Corporation in this district.

California Metal Producers Association

The complete articles of association of the newly formed organization of California mine operators, are given below. All persons and concerns eligible to membership are invited to join.

Name.—The name of this Association is: California Metal Producers Association.

Purpose.—The purpose of this Association is to subserve, promote, and protect the interests of those engaged in mining for or the production of metals in this state and in that behalf to secure betterments in all branches of the industry; also to promote the health, safety, and welfare of miners and employees engaged therein, and to promote harmonious relations between employers and employees in said industry, and to prosecute any and all other lines of activity which may subserve the welfare of the industry and those engaged therein, as owners, operators, and employees.

Membership.—All persons, co-partnerships, and corporations of approved standing engaged in mining for or in the production of metals in this state may be admitted to membership, upon the terms, and under the conditions hereinafter set forth. Applicants for membership, upon the approval of their application and election to membership, shall become members upon signing these articles either in person or by authorized officer—or attorney in fact.

Fees and assessments.—There shall be a membership fee of $25 for those employing 25 men or more and $10 for those employing less than 25 men. Monthly dues shall be paid by the members upon the basis of the number of men employed in the mining or in the production of metals as shown by their monthly payrolls. Monthly dues shall be payable to the secretary-treasurer, at his office, on the twentieth day of each calendar month. In computing the number of men employed, the total number of shifts worked during the preceding month, as shown by each member's payroll, shall be divided by 30, and the result shall be defined as unit men; monthly dues shall be apportioned and payable on said basis of unit men.

Officers.—The officers of the Association shall be president, who shall also be chairman of the executive committee, two vice-presidents and secretary-treasurer. Said officers shall be selected annually by the executive committee immediately after the annual meeting of the Association on the fourth Wednesday of October, and the president and vice-presidents shall be members of the executive committee. The president, vice-presidents, and secretary-treasurer shall perform the duties and exercise the powers, usually required of, and conferred upon, such officers in deliberative and executive bodies.

Executive committee.—There shall be an executive committee of seven members, to be selected annually by the Association at its meeting on the fourth Wednesday of October.

Finance committee.—There shall be a finance committee of three members, to be selected annually by the Association at its meeting on the fourth Wednesday of October.

Principal office.—The Association will maintain its principal office at San Francisco, California, where the secretary-treasurer shall reside, and all records be maintained and all meetings be held.

Meetings.—The regular annual meeting of the Association shall be held at the office of the Association on the fourth Wednesday in October of each year. Special meetings of the Association may be called by the executive committee and shall be called by the secretary-treasurer upon the written request of ten or more members. Notice of the regular annual and special meetings shall be given in writing by the secretary at least two weeks before the date of the meeting. Fifty-one per cent of the membership shall be present or represented by approved proxies to constitute a quorum. The vote of a majority of those present or represented by approved proxies shall be necessary to a decision binding upon the Association. The Association may also vote and express its opinion or decision in the following manner; that is to say, after due and proper notice given by the secretary in writing, to each and all of the members of the Association, the members may cast their ballot by written United States mail vote. In that behalf it is prescribed that at least two weeks' written notice of such action shall be given by the secretary, provided that in emergency cases a less time may be prescribed by resolution of the executive committee. All mail votes shall be addressed to the secretary-treasurer, at the office of the Association. The voting power of members shall be, and is hereby prescribed to be in units, in the following manner; that is to say, each member employing 25 men or less shall be entitled to one vote; for each additional 25 employees, or fractional portion thereof over and above the initial 25 employees upon the payroll during the month preceding the date of any pending vote, or ballot, the member shall be entitled to one additional vote.

Powers and duties of the executive committee.—(a) At all times while the Association is not in session, the executive committee shall, and it is hereby authorized, empowered, and instructed, to exercise the whole power of the Association.

(b) A majority of the executive committee shall constitute a quorum. A majority of the quorum shall be necessary to form any decision, or pass upon any question, binding upon the Association. A written protest by two members of the executive committee upon any question, which said protest shall be lodged with the secretary-treasurer not later than three days after casting of the vote complained of, shall have the effect of suspending the operation of such action of the majority of the executive committee, until said action of the majority shall be ratified by the vote of a majority of the members of the Association. The vote of the members of the Association shall be cast by United States mail vote or by telegraph vote. The secretary-treasurer may prescribe whether said vote shall be by mail or telegram, and likewise shall prescribe the time allowed for casting such vote, provided that the time allowed for vote by mail shall not be less than seven days nor more than twenty-one days, and if by telegraph not less than three days nor more than six days.

(c) The executive committee shall select one of its own number to act as chairman in the absence of the president and vice-presidents.

(d) Sessions of the executive committee shall be attended by the secretary-treasurer, who shall keep a record of the proceedings of the committee and shall, quarterly, send an abstract of the executive committee's proceedings to all members of the Association, and at such other times as directed by the executive committee. In the absence of the secretary-treasurer, the executive committee shall select one of its own members as secretary pro-tem.

(e) The sessions of the executive committee may be held at San Francisco, California, or at any other place designated by the chairman of the executive committee. Such meetings may be held at any time upon ten days' written notice given by the secretary-treasurer, provided that a less time may be given in cases of emergency, either by the secretary-treasurer, or by the chairman of the executive committee. Notice shall be given either by letter, orally, or by telegram.

(f) The executive committee shall have power to fill any and all vacancies in its own body when the Association is not in session.

(g) The executive committee may be sub-divided into sub-committees. The executive committee shall determine the

number, the name, and the duties of such sub-committees and may create and abolish such sub-committees at will. The actions of the sub-committees shall not be binding upon the Association until ratified, approved, and adopted by the executive committee.

(h) The executive committee at large shall be and is hereby constituted a membership committee. As such membership committee it may prescribe the qualifications, not in conflict with article III hereof, and the credentials desirable and expedient for membership in this Association, and shall pass upon the applications for membership. No applicant shall be elected to membership until the name of said applicant has been mailed to each member of the Association and two weeks' time allowed for receipt of objections. An affirmative vote of four members of the executive committee shall be necessary to admit to membership.

(i) The executive committee is vested with full power and authority to prescribe and administer the finances of the Association. The executive committee shall determine the total aggregate of any and all regular assessments, necessary to be levied and assessed for the prosecution of the Association's business and purposes for any month, and may also levy, assess, and collect any and all special assessment whensoever any necessity or occasion may arise for such special assessment.

(j) The executive committee may act by United States mail vote in the same manner as hereinbefore prescribed for the action of the Association at large, providing that in cases of emergency the notice of the mail vote may be given upon such time as the chairman of the executive committee may prescribe, such notice to be given either by United States mail or orally, or by telegram. The executive committee may vote by telegram.

(k) The executive committee may from time to time amend these articles, and prescribe any and all further rules and regulations for the conduct and government of the Association and of the executive committee, as may, in the judgment of the executive committee, from time to time appear necessary, advisable, or expedient, all amendments being in force until disapproved by a meeting of the Association.

Delinquencies, expulsions, and withdrawals.—No member shall have a right to participate in the deliberations of the Association or vote on any matter while in arrears for dues for 30 days; any member may be expelled upon two-thirds vote of those voting thereon after a 30 days' notice by the secretary, and a vote thereon shall be by mail. A member may withdraw by resignation directed to the secretary, dues first being paid.

Amendments.—These articles of association may be amended by a two-thirds vote of those present in person or by proxy at any regular meeting of the Association or at a special meeting of the Association called for the purpose of making such amendment or amendments.

AN EXPLOSION in what is known as Ralph's mine of the Taupiri Coal Co., operating a coal mine near Auckland, New Zealand, entombed 59 men, in the second week of September. Of these, 19 escaped, but one has since died. The workings were quite free from gas, and naked lights were always used. The drifts and other workings are partly under the Waihato river.

THE CAM & MOTOR MINE, Rhodesia, produced 11,870 tons of ore yielding $80,200 in September. The recovery was 65.3 per cent.

STONE QUARRIED in the United States in 1913 was valued at $83,532,995, an increase of 7% over that of the previous year.

Artificial Respiration

The U. S. Bureau of Mines has been studying the various methods of inducing artificial respiration suitable for use in mines when men are overcome by electric shock or by gas. A committee consisting of Dr. W. B. Cannon, chairman, professor of physiology, Harvard University; Dr. George W. Crile, professor of surgery, Western Reserve University, Cleveland, Ohio; Dr. Joseph Erlanger, professor of physiology, Washington University, St. Louis; Dr. Yandell Henderson, professor of physiology, Yale University; and Dr. S. J. Meltzer, head of the department of physiology and pharmacology, Rockefeller Institute for Medical Research, has reported the following recommendations. As these not only apply to men who are overcome by electric shock or gases in mines, but also to persons suffering from the effects of illuminating-gas poisoning or from electric shock anywhere, they are of importance to many thousands of workmen.

In case of gas poisoning, remove the victim at once from the gaseous atmosphere. Carry him quickly to fresh air and immediately give manual artificial respiration. Do not stop to loosen clothing. Every moment of delay is serious.

In case of electric shock, break electric current instantly. Free the patient from the current with a single quick motion, using any dry non-conductor, such as clothing, rope, or board, to move patient or wire. Beware of using any metal or moist material. Meantime have every effort made to shut off current.

Attend instantly to the victim's breathing. If the victim is not breathing, he should be given manual artificial respiration at once. If the patient is breathing slowly and regularly, do not give artificial respiration, but let nature restore breathing unaided.

In gas cases, give oxygen. If the patient has been a victim of gas, give him pure oxygen, with manual artificial respiration. The oxygen may be given through a breathing bag from a cylinder having a reducing valve, with connecting tubes and face mask, and with an inspiratory and expiratory valve, of which the latter communicates directly with the atmosphere. No mechanical artificial resuscitating device should be used unless one operated by hand that has no suction effect on the lungs.

Use the Schaefer or prone pressure method of artificial respiration. Begin at once. A moment's delay is serious. Continue the artificial respiration. If necessary, continue two hours or longer without interruption until natural breathing is restored. If natural breathing stops after being restored, use artificial respiration again.

Do not give the patient any liquid until he is fully conscious. Give him fresh air, but keep his body warm. Send for the nearest doctor as soon as accident is discovered.

THE ST. JOHN DEL REY MINE, Brazil, produced $183,000 from 16,000 tons of ore in September.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Rand Banket

Reply by Mr. Horwood to J. W. Gregory's Discussion Dated Glasgow, May 5, 1914

In his cleverly worded discussion[1] Professor Gregory re-asserts the old arguments embodied in his paper read in London in 1907, before the Institution of Mining and Metallurgy on 'The Origin of the Gold in the Rand Banket.' This paper, as he admitted, was the result of his observations during a brief visit to the Rand in 1905, and of information and ideas obtained second-hand on that occasion. My difficulty in replying clearly and concisely lies in the fact that not only has he either not read my paper carefully, or he has purposely ignored much of the evidence there advanced, and consequently much of it has to be re-stated; but also he brings forward the same arguments that he used in his paper, quite regardless of the fact that many of them that he now uses were shown in the discussion at the time by admittedly competent authorities to be untenable. Further, his theory is what one might term a 're-solution theory.' That is, that while the gold was originally alluvial, it has since been subjected to solvent influences, and been re-distributed in the banket. Thus mere arguments against the alluvial theory and in favor of the infiltration theory can sometimes be fairly well answered by the re-solution theory. On the other hand, I think most of my readers will admit that the actual evidence points unmistakably to a lode origin. Destructive criticism in the form of expressions of personal opinion unsupported by scientific evidence helps no one, and Gregory brings forward no new evidence in support of his placer theory. Alluding to the infiltration theory, he ends his discussion by stating that it "introduces the gold from a hypothetical and improbable source, along solution channels of which we still have no evidence, and, according to Mr. Horwood's version, at a date long after the banket had received its gold." In his paper he made the statement that it is only when the ores can be traced to fissures through which the solutions have come, that the evidence for infiltration is accepted as conclusive; and that no such fissures are known on the Rand. In my treatise, one of the points upon which I lay great stress is that the auriferous bankets differ in no important essentials from ordinary gold-quartz lodes, the gold having been derived from the barysphere or deep region that is admittedly the primary source of the heavy metals. The numerous and extensive fault-planes and longitudinal dikes that intersect the bankets mark the site of fractures, communicating with great depths. When discussing Gregory's paper and his reference to verticals in the case of the silicious gold ores of South Dakota, W. McDermott pointed out that on the Rand the connection with deep-seated sources of gold was provided by the 'reefs' themselves, as with ordinary fissure veins. After marshaling my evidence, I expressed the opinion that the facts indicated that the genesis of the gold, of the pyrite, and of the carbon in the bankets of both Witwatersrand and Black Reef age in the Southern Transvaal, and also of the bedded quartz veins in the Black Reef and Dolomite formations of the Northern Transvaal, could be satisfactorily explained on the assumption of one period of mineralization, and that the gold was introduced after, or during, the time when the Dolomites were being laid down. Gregory ends his argument by the statement that this date was "long after the banket had received its gold." He does not attempt to prove this, it is merely his opinion based on his statement that "lumps of auriferous banket occur in the Black Reef conglomerates;" and this, he thinks, seems to contradict my conclusions.

The Black Reef conglomerate is in the Black Reef formation, which occurs at the base of the Dolomite formation. Formerly, in places, it was mined, as it sometimes carries gold, and may then be termed auriferous banket. However, I imagine Gregory (disregarding the Elsburg conglomerates that are placed by some in the Ventersdorp system and by others in the Witwatersrand system) refers to lumps of banket, stated to be auriferous and assumed to have been derived from the Witwatersrand banket, reported as occurring in the Ventersdorp series that underlies the Black Reef formation. I maintain that the evidence to date indicates that the Rand banket owes its gold directly or indirectly to the longitudinal dikes, and that the latter are genetically related to the Klipriversberg amygdaloidal diabase, which is of Ventersdorp age. If some of the Ventersdorp breccias or conglomerates (other than the Elsburg) do actually contain boulders of Witwatersrand banket that are auriferous, the gold in these boulders may represent fragments torn from the banket beds during the irruption of igneous rock, either after that phase of the Ventersdorp period when the main mineralization occurred, or, if before, their gold may be directly due to the Ventersdorp diabase; if it be maintained that they are water-worn, and if they are, then they may have been derived from the disintegration and denudation of

[1] My reply to Gregory's discussion dated May 5, 1914, has been unavoidably delayed owing to illness.

the Witwatersrand beds during some portion, later than the mineralization phase, of that long drawn out time of volcanic and eruptive activity that characterized the Ventersdorp period.

Gregory admitted that pyrite is so easily oxidized and so brittle that its occurrence in the form of pebbles in a placer deposit was highly improbable, and that he had not seen any in such a deposit; but, that when he was on the Rand, he realized that some of those in the banket seemed to owe their form to attrition, and from their shape he concluded that they were pseudomorphic after black iron sand, as he argued, that their arrangement agreed with that of the black iron sands in modern placers, and he instanced those of New Zealand, along the west coast of the South Island: These conclusions were dealt with in the discussion on his paper. S. H. Cox stated that he was acquainted with the auriferous black sands of New Zealand, and he failed to see any resemblance between the conditions there and those on the Rand. S. J. Speak pointed out that Gregory accounted for the conversion of black iron sand into pyrite by the agency of sulphuretted hydrogen from the decomposition of organic matter, and the precipitation of the gold and pyrite by the action of water containing oxygen on the pyrite, producing ferric sulphate that dissolved the gold, and the solution encountering fresh reducing matter. As he pithily said, Gregory summoned to the assistance of his theory sulphur and oxygen *ad lib.* and reducing and oxidizing agencies as he desired; and Speak showed that even if the organic matter contained as much as 4% of sulphur, the same thickness of organic matter as of banket would have been necessary, and aptly asked what had become of the carbonaceous matter, and the space once occupied by this organic matter; also, whence were the oxygenated waters derived? J. Malcolm Maclaren said that one of the cardinal features of Gregory's paper was his supposition that the pyritic seams associated with the banket represented original marine black sand, consisting presumably mainly of magnetite and ilmenite; but that as these minerals were extremely stable their direct replacement by pyrite was certainly highly problematical, and that such alteration would appear to be possible in nature only by way of an intermediate hematite stage. He also emphasized the fact that though Gregory advocated the alluvial theory, he also employed the impregnation theory to bring the gold again into solution, and consequently, to validate his assumptions, the alluvial gold must have been re-deposited in the same place from which it had been dissolved. R. Beck confessed that the hypothesis that all the iron ore had been changed into pyrite in the banket seemed very improbable, and, if it had, surely some portion of the beds could be found in which such gigantic pseudomorphic processes would not yet have taken place. David Wilkinson,[2] discussing the occurrence of gold in the pyritic quartzites, informed me that many years ago he examined these quartzites carefully in the Wolhuter mine and found that while often the pyrite occurred in layers parallel to the bedding, in many other cases it occurs irregularly across the bedding, and he considers it undoubtedly due to infiltration. He contends that it cannot be due to sedimentation on account of its form. Some of it, in places, yields from 10 to 15 dwt. gold per ton. G. F. Becker, in order to explain, on the placer theory, the presence of the pyrite in the Rand banket, suggests that the magnetite of the black sand may have been in part converted into pyrite by the sulphur-bearing solutions accompanying the intrusion of the dikes.[3] Since I have shown that the latter contain appreciable amounts of gold, pyrite, and carbon, and since the dikes communicate directly with those regions that are the original source of the metals, if one invokes their agency at all, is it not more reasonable to conclude that the gold, pyrite, and carbon at all events for the most part, are derived from them?

Most impartial critics will probably admit, as W. Lindgren and J. F. Kemp have done, that I clearly demonstrated that the pyrite had replaced quartz pebbles and quartzite pebbles, and also the matrix of the banket, and these can be found in all stages of replacement. At the same time I dealt fully with the question of the shape of the pyrite pebbles. Gregory speaks of some of the pyrite nodules as 'concretions.' I very fully discussed this point, in my paper, and showed that to state that they are concretions merely leaves the problem where it was before, and I proved that the so-called pyrite pebbles occur not only as metasomatic pseudomorphs, but also, be it noted, as metasomatic concretions.

The analogy that I drew between the pyrite and flint nodules was not one of genesis, but one merely to illustrate the influence of existing lines of least resistance in determining where the greatest deposition will occur. In the particular Crown Reef case under discussion the evidence indicated that deep seated solutions ascended through fractures and along lines of weakness, now marked by the intrusion of a dike, and spread out laterally through a conglomerate bed, that immediately overlaid an impervious shale band, and there deposited their mineral contents; while in the chalk the solutions (which in this case had derived their silica from organisms that already existed in the beds) have flowed along horizons coinciding with the bedding-planes, as these offered easy passages for maximum circulation, and they there precipitated their silica in the form of flint.

C. Baring Horwood.

London, September 22.

(To be Continued)

[2]In this reply to Gregory's discussion the various references to information given me by David Wilkinson are from a letter written by him to me from Johannesburg and dated July 24, 1914. He had read my treatise on the Rand banket, and this letter was written just after he had read Gregory's discussion on my paper. I take this opportunity of thanking him for placing at my disposal the valuable evidence he had carefully collected during a number of years spent on the Rand.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

LABOR EMPLOYED at Panama canal, including 4059 on the railroad, totaled 28,883 on August 26, compared with 32,437 on July 22.

COST OF SINKING a two-compartment shaft 595.3 ft. at the Rock Island Coal Mining Co.'s mine, Hartshorne, Oklahoma, totaled $15,264, or $27 per foot. The cost varied from $13.14 to $50.51 per foot. The country passed through was generally slate, and the two 6 ft. 2 in. by 8 ft. 6-in. hoistways were sunk in 199 days.

BRONZE FIVE-CENTAVO PIECES are now being coined in Mexico City by the Constitutionalist authorities. The composition of the coin is decreed as follows: copper, 95%; tin, 2.5%; and zinc, 2.5%, with an allowance of 1% in all these metals. The coin is 28 mm. diameter, and weighs nine grams. A nickel coin may also be executed.

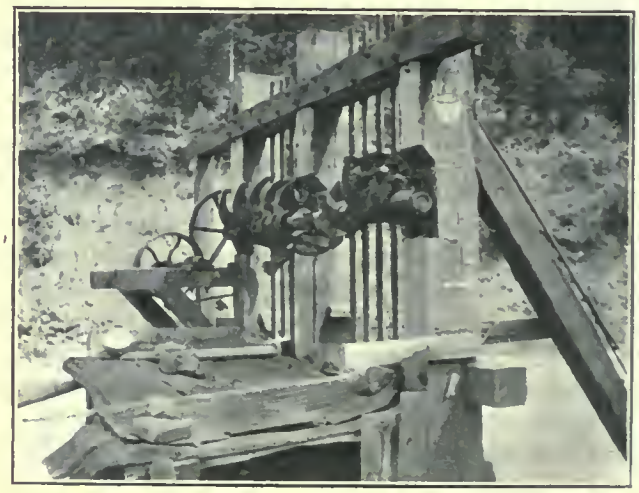
CULM, or coal refuse, produced in mining anthracite, amounts to about 25% of the output of this coal. A large tonnage of good material has been recovered from the culm piles, while more has been flushed back into the mines for filling old workings. In 1913, the International Acheson Graphite Co., of Niagara Falls, produced about 7000 tons of graphite by the use of electricity on coal, 8750 tons of culm being consumed in the work.

CRANEMEN in foundries, when handling maximum loads, particularly ladles of molten metal, should test hoist brakes after a load has been lifted a few inches; if brakes do not hold, the load should be lowered at once and the brakes adjusted or repaired. If hoist brakes refuse to hold while the crane is handling molten metal, it may be necessary, in order not to interrupt the pouring operation, to sustain the load by short upward movements of the hoist, to counteract settling of load.

MANY MINERS are careless in handling explosives. The following 'don'ts' should be remembered: miners resting should not smoke in a place used as a powder magazine; crimping a 'cap' with the teeth is very dangerous; hatchets or cold chisels should not be used to open a box or keg; in carrying dynamite in a sack, a miner should not carry capped fuse in the other hand; do not punch a hole in a cartridge with a candlestick attached to a lighted carbide lamp; dynamite must not be thawed by placing sticks inside a shirt. In United States metal mines in 1912, 427 men were killed and injured by explosives.

THE COPPER PRODUCT of Michigan is largely native, and is considered for some purposes superior to electrolytic copper. 'Lake' copper, as the product of Michigan is generally known in the trade, sells generally at about a quarter of a cent per pound above other coppers. The mining of copper in Michigan is of prehistoric origin, the metal having been used by the North American Indians before the advent of the white man. The development of copper mining, however, began in 1845, and since that date to the close of 1913 the production has amounted to over 5,335,000,000 lb., or about 30% of the total output of the United States. The total output of Montana to the end of 1913 was about 6,200,000,000 pounds.

CURIOSITIES in the shape of old stamp-mills are still left standing in various parts of the world, and excite considerable attention. The accompanying halftone, from a photograph taken by O. F. Heizer, of the Argo Reduction & Ore Purchasing Co., shows an old dismantled plant up Trail creek on the road to Freeland, about three miles from Idaho Springs, Colorado. Close inspection of the picture will reveal some peculiar features in the battery. It will be noticed that the order of drop of the stamps is 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, and that the stems are upset and threaded, and the tappets screw onto them; also that the upper end of the stems show a thread which engages a similar thread in the boss-heads. Mr. Heizer cannot remember ever having seen or even heard of any similar arrangement, and thought it might be a matter of interest to readers of the *Press*. Tappets screwed on to the stems were very common in early Australian mills, in fact, numbers are still at work in certain old districts.



OLD STAMP-MILL NEAR IDAHO SPRINGS, COLORADO.

KLONDIKE RIVER, MAY 6, 1914, AND CANADIAN-KLONDYKE No. 4.

MINING IN THE FAR NORTH*

Operations of the Canadian-Klondyke Gold Mining Company, Ltd.

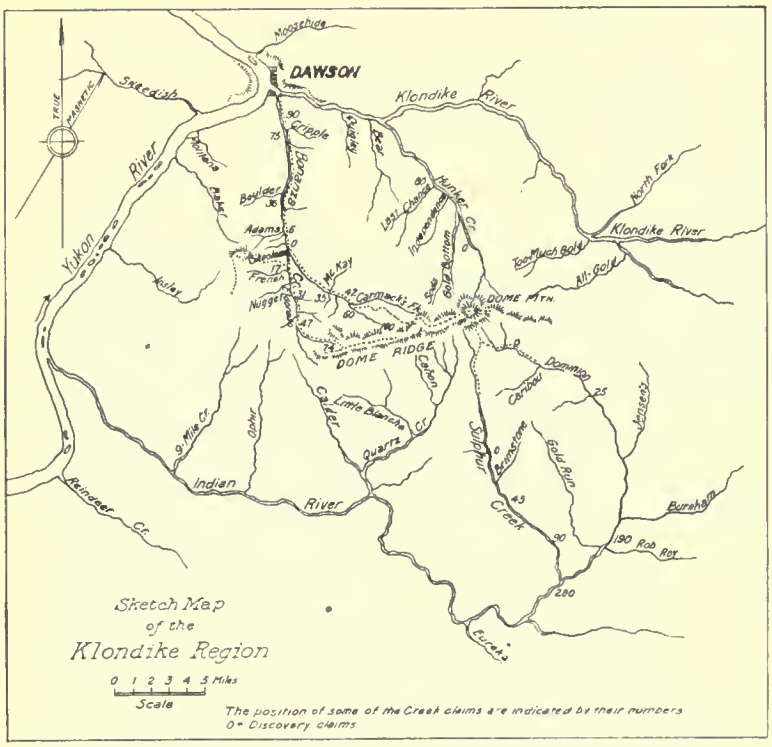
By EMIL EDWARD HURJA

One 7½-ft. and three 16.1-ft. dredges are working on holdings of the Canadian-Klondyke Gold Mining Co., Ltd., in the Klondike, with prospects of two more 16.1-ft. boats to be added during the next two years.

Perhaps the most interesting development by the Company is its system of ditches, which last year permitted the dredges to operate until December 26, despite the cold weather. The boats kept on working because of the admirable power facilities which the Company developed at its plant on the north fork of the Klondike river. The ditches total 60 miles in length. Their width varies from a minimum of 30 to a maximum of 70 ft., and can carry 30,000 inches of water. The power-house is 30 miles from Dawson.

The particular method taken to permit operation of the hydro-electric plant the whole year round was conceived by J. W. Boyle. About the time when power plants in the

*[Previous articles in this series by Mr. Hurja on mining in Alaska and the Yukon have been 'Mining Revival in the Ketchikan District, Alaska,' July 4; 'Wrangell, Alaska,' special correspondence, July 11; 'Developments of the Alaska Gold Mines Co.,' July 18; 'Juneau, Alaska,' special correspondence, July 25; 'Cordova, Alaska,' special correspondence, August 8; 'Valdez and Prince William Sound,' August 15; 'Seward and the Kenai Peninsula,' August 29; 'The Koyukuk Mining District,' September 12; 'Operations of the Yukon Gold Company,' October 10. Mr. Hurja in subsequent letters will give full accounts of present conditions in each of the great producing districts of the Far North.—EDITOR.]



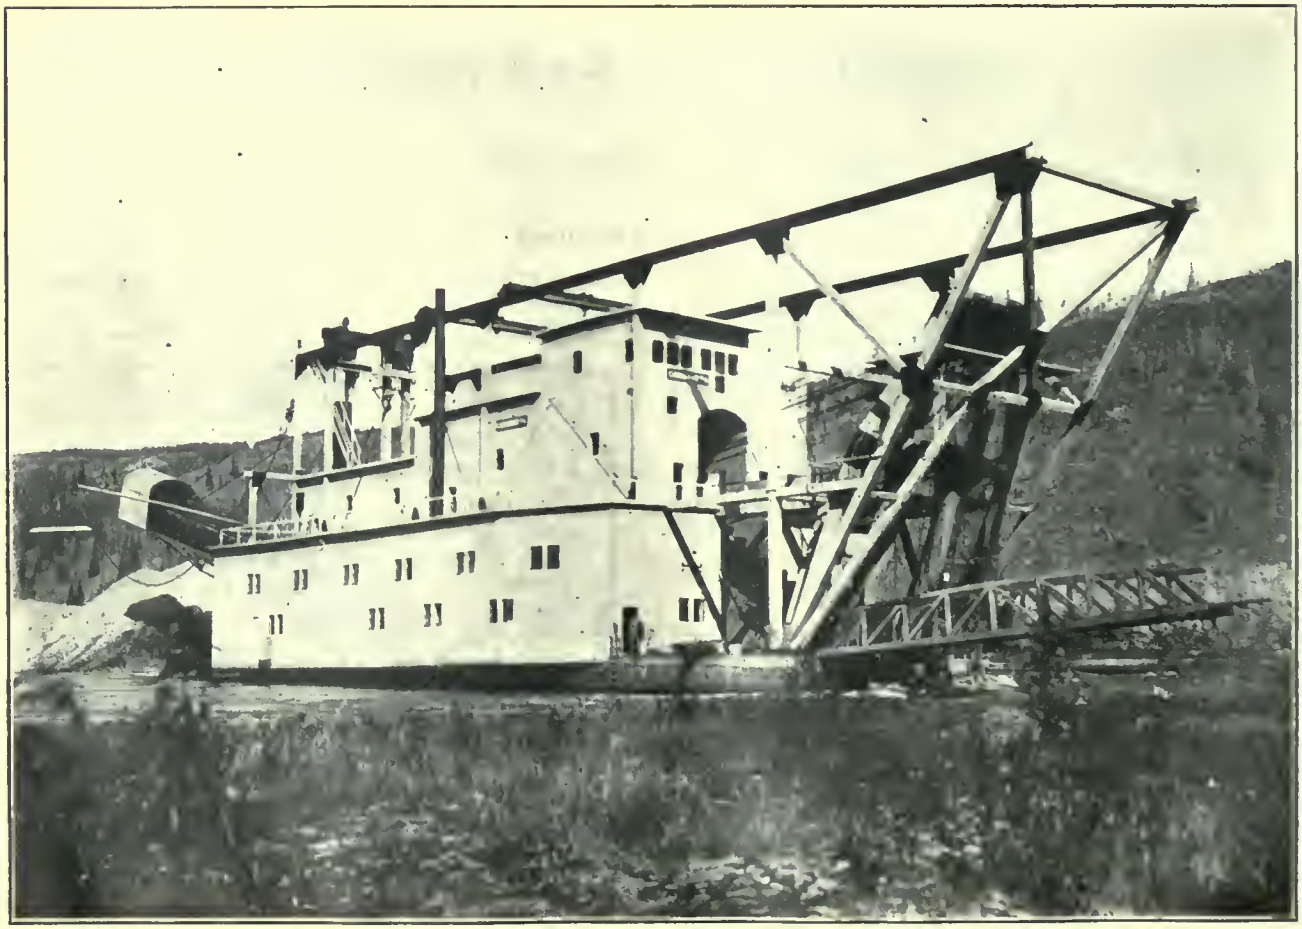
Klondike usually close, the ditch was flooded to its capacity for a few days. The cold weather caused a sheet of ice to form across the top of the ditch. Then, after the covering had attained sufficient thickness, the water was lowered to its normal level. Three electric heaters were placed at intervals in the ditch, and the water was kept sufficiently warm to prevent freezing. In addition to supplying the dredges with power, the town of Dawson draws its current from the Boyle plant. The maximum capacity of the plant is 10,000 hp. It was built in 1910. Power is supplied by the Canadian-Klondyke Power Co., 51% of the capital stock of which is owned by Mr. Boyle, 29% by the Granville mining company, and 20% of which is not issued.

During January 1913 the temperature for seven days did not rise above 68°F. below zero, and as the power-plant was not forced to suspend operation during that time, the success of the ditch-freezing scheme cannot be questioned.

At the mouth of Bonanza creek, a transformer plant with two 1875-kw. transformers and an electrical repair-shop have been built. From this plant, the electric truck used by the Company in its freighting work around the claims is charged.

The area owned by the Company is extensive. The principal holding is known as the Boyle concession, which takes in all of the valley of the Klondike river from summit to summit for a stretch of 6¾ miles, from the mouth of the Hunker to the mouth of Bonanza. Three miles of ground on the upper end of Eldorado creek, worked in the earlier days of the Klondike by crude methods, remains to be reworked by dredging. Partly by ownership and partly by agreement, the upper five miles of Hunker creek is being worked. The Company also owns five dredging leases, taking in the first 15 miles of the Klondike river as well as five miles up and five miles down the Yukon river from the mouth of the Klondike.

The 7½-ft. Marion dredge was the first built. As the result of the experience of this dredge, which started work



No. 4, A MARION, 16.1-CU. FT. BUCKET DREDGE.

August 14, 1905, now on upper Hunker, Joseph W. Boyle planned the 16.1-ft. dredge. The big dredges, which are among the largest in the world, were first conceived in 1909. Canadian No. 2, the first, began operation in November 1910.[1] Orders for No. 3 and No. 4 were placed in 1912, and they started work in May 1913. No. 1 is at present on upper Hunker; the others in the valley of the Klondike river, No. 2 below the mouth of Bear creek, No. 3 inside the city limits of Dawson one-half mile from the mouth of the Klondike, and No. 4 opposite the mouth of Bonanza creek, 1½ miles above No. 3. The machinery of the big dredges was built by the Marion Steam Shovel Co. The wearing parts of No. 2, 3, and 4 have been standardized, and parts are renewed to last through the 270-day working season.

Construction Details

The 16.1-ft. dredges have hulls 136 ft. long, 56 ft. 8 in. wide, with a deck overhang on each side of 6 ft. The depth at the bow is 14 ft. 6 in.; at the stern, 12 ft. Lumber used in construction of the hull totals 750,000 ft. Entire control of all dredge machinery is centred in the winch-room, which is connected with every other part of the dredge by an electric bell system. All wires run through conduits. A transformer reduces the current from 2200 to 110 volts and makes possible a complete electric lighting system. Two pumps are operated by General Electric induction motors of 150 hp. Motors operating other parts of the dredge machinery are as follows: Main drive, 300 hp.; ladder hoist, 200 hp.; screen drive, 150 hp.; stacker hoist, 50 hp.; stacker belt drive, 50 hp.; winch motor, 50 hp.; fire pump, 35 hp. All motors are 2200-volt, General Electric make. Oil switches are all encased in steel boxes, with steel pans under them large enough to contain all the oil from the switch.

A 20-ton traveling crane travels 16 ft. beyond the bow of the dredge, picks up machinery and parts for the dredge with ease from the bank. Hatches are in the roof, making it possible to lower machinery easily into the hull. The bucket-line has 68 buckets, each with a capacity of 16.1 cu. ft. The buckets weigh 4600 lb. each. They travel at the rate of 21½ per minute. Boulders weighing from 500 to 600 lb. are carried with ease.

The dump box has in it two 2-in. nozzles and one 3½-in. nozzle, opening into a revolving cylindrical screen weighing 80 tons, 50 ft. long and of 9 ft. 9 in. diameter. Thirty-five feet of the screen is perforated. Suspended through the cylinder is a 14-in. pipe, discharging water through two rows of 1-in. perforations. The water is supplied by a 14-in. high-duty Morse centrifugal pump.

Water for the sluice tables on both sides of the screen is supplied by a 16-in. Worthington centrifugal pump, discharged through pipes running along the heads of the tables. There are 15 tables on each side, inclined 1½ in. to the foot, each having a width of 30 in. and a length of 42 in. Saving of gold is effected by cocoanut mat and expanded metal riffles followed by angle iron riffles. The mats catch 95% of the gold. They are replaced with clean ones each morning when the dredge stops to permit of oiling the lower tumbler. The stacker is 120 ft. long, has a belt 48 in. wide, and travels at the rate of 180 ft. per minute. Waste from the screen is handled by two sluiceways, one on either side of the dredge.

Anchors are two in number, each 65 ft. long and weighing 32 tons. The ladder is lowered two feet at a time when digging is going on in the upper gravels until within three feet of bedrock, then one foot at a time to bedrock, then 6 in. at a time while in bedrock. Most of the gold occurs from three feet above bedrock to five or six feet in bedrock.

In order to keep the dredges free from ice during the cold weather, a canvas-covered, square, box compartment encloses the stacker belt. The compartment is heated with steam coils. A 60-hp. boiler is housed in a steel and asbestos-lined room forward in the hull, so arranged that it can be flooded with water in an instant in case of fire. One room has been provided on each dredge as a rest and lunch room, equipped with electric stoves and toasters, so that employees can have hot lunches without inconvenience. Mr. Boyle estimates the cost of each 16.1-ft. dredge at $475,000.

Life of the ground in sight for the dredges is estimated at 18 years, not counting holdings outside of the Boyle concession. The down-stream four miles of the concession has been thoroughly prospected. Holes have been put down at 100-ft. intervals up and down stream, and at 200-ft. intervals across the valley floor. Work of prospecting the upper 2¾ miles of the concession is in progress now. A No. 3 Keystone drill and shafts are used in prospecting. Crews in charge of the work put down three shafts at a time. Prospects shown up so far this year have been as good as the ground already proved. The four miles of ground prospected is estimated to contain 150,000,000 cu. yd. of gravel, with an average value of 22c. per cu. yd.. If present indications are borne out by further prospecting, orders for the machinery for one or two new boats will be placed this year, for shipment during the summer of 1915. These dredges will start digging in 1916.

Operation up to this time has shown a recovery of 25c. per yd. In Klondike valley, at a working cost of 6c. per yd. The major part of the cost comes in the stripping work, which is being carried on three years ahead of the actual operations. The sandy loam, layers of black 'muck,' and timber are stripped off by ground-sluicing and the use of a 1½-ft. Marion steam-shovel. In 1904 all the Klondike Valley gravels were frozen. The output of each of the three big dredges averages 10,000 yd. per 24-hour day. No. 2 dug 100,000 yd. in a single week, and recently established a record for a single day's work of 14,411 yd. This was under very favorable conditions.

On Hunker creek, steam thawing has been resorted to in order to keep the 7½-ft. dredge in ground. For several years past ground has been stripped ahead of it, and after next year no more steam thawing will be necessary.

At the mouth of Bonanza creek, a mess-house and bunk-house and other buildings for the crews of dredges No. 3 and 4 have been built. The crew of dredge No. 2 is housed at Bear creek, and of No. 1 at Hunker. Considerable *esprit de corps* has been developed among the Boyle employees. During the summer, the dredge crews form baseball teams and compete with each other, while curling clubs are formed in winter.

The Canadian-Klondyke Mining Co., Ltd., purchases all its supplies for the different mess-houses from Dawson merchants. Mr. Boyle says that excellent treatment is obtained and immediate redress is had where merchandise is unsatisfactory. The confidence and good will of Dawson people is due in a measure to this treatment by the Company.

---

[1][No. 2 dredge of the Canadian-Klondyke company sank during the second week of October. It will be out of commission for the remainder of the season.—Editor.]

According to T. A. MacLean in his work, 'Lode Mining in Yukon,' published by the Department of Mines, Canada, the geology of the Dawson district is complicated, and rock formations are found ranging in age through the greater part of the geological scale, and exhibiting varied structure and composition. In many instances it is nearly impossible absolutely to classify certain formations, on account of gradual alteration of massive igneous rocks into schists, and clastic rocks into the appearance of igneous rocks. The Klondike and allied series are the most important, the principal rock being a light-green sericite schist. Practically all the gold-producing creeks occur within the area occupied by these schists, while the quartz veins, so far disclosed, lie generally along the slopes and ridges of the hills, which form the divide between the different water courses.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

FURTHER NOTES ON THE EXPORT OF COPPER.—THE NICKEL INDUSTRY.—RUSSIAN COPPER MINES.—REOPENING THE YELLOW JACKET MINE, LEMHI COUNTY, IDAHO.—F. A. HEINZE.

The principal sellers of copper have been making strong protests at Washington, in an endeavor to get our government to take some official action in regard to the numerous cargoes of copper which have been held up by the British government. The cost of shipments to the Mediterranean ports is already more than double, and several of the lines will not accept shipments at any rates. If England maintains her present attitude, about the only markets left for the American producers will be those of France and England, both of which must be pretty well stocked by this time. The American Metal Co., American Smelting & Refining Co., United Metals Selling Co., and the Consolidated Metals Co. are taking united action, and it has been proposed to charter their own ship and make a strong effort to get the United States government to protect this from seizure. It is doubtful whether it will be possible to secure any very strong action on the part of the State Department. So far no definite assurance has been received. Meanwhile, exports of copper have remained at a fair figure.

The Russian copper companies have not decreased their output. The Kyshtim corporation reports that during the four weeks ended August 15, 734 long tons of refined copper was produced by the refinery. During the same period the smelters smelted 25,779 tons of ore yielding 538 tons of copper. The ore smelted averages about 2½ to 3½% copper.——The Spassky company produced 350 tons during the month ended October 13.——The Sissert output was 72 tons in the month ended August 13, 74 tons in September, and 50 tons during the month ended October 13. This copper was recovered in its leaching plant from ore averaging a little over 4% copper.

It is interesting to note that the Canadian government is attempting to prevent nickel from reaching Germany and Austria, and has prohibited the export of nickel from Canada to countries at war with Great Britain. It is not a very effective action to take, because none of the nickel is produced in Canada; the Mond company ships its matte to Wales for reduction, and the International Nickel Co. sends its matte to New Jersey for reduction to nickel. Of course, it is easy for the British government to control the shipments from the Mond plant, but the International company is a different matter. As a matter of fact, this Company has not sold any nickel to either Austria or Germany since the beginning of the war, and the sales to the allied countries have been smaller than reported. Thus the recently reported sale of 1000 tons of nickel to Russia is an exaggeration. The International is only operating its principal mine, having shut down the others and having reduced capacity at its smelter.

There has been a great deal of interest in the West of recent years over the successful reopening of old mines, notably the Plymouth Consolidated in California. Another old gold mine which has successfully come back is the Yellow Jacket, in the western part of Lemhi county, Idaho, not far from the old Leesburg gold diggings, which were the scene of excitement in 1859. The ore in the Yellow Jacket is free-milling quartz, occurring associated with a complex series of intruded igneous rocks in metamorphic schist. The mine produced a good deal of ore yielding from $8 to $10 per ton in the mill, but the orebody was badly faulted and was lost. More recently the Mandarin Mines Corporation, organized last July, and capitalized at $1,000,000, which has been financed by C. W. Pope and D. C. Catlin of New York, reopened the mine, and by well directed exploration has discovered the faulted portion of the orebodies. Recent developments are said to be very encouraging, and the management has strong hopes of making a good profit from the new work.

The death of F. A. Heinze last week called forth many reminiscences of his varied career. There has been much speculation as to how much is left of the $10,000,000 he is supposed to have brought to New York at the conclusion of his fight against the Butte companies. One by one since that time his holdings have slipped away, and the recent lawsuit in which Edwin Gould recovered a judgment for over $1,000,000 against him must have left him with very little in the way of cash assets. Heinze still retained an interest in the Ohio Copper Co., the Stewart Mining Co., and extensive land holdings in British Columbia, but by the time these are disposed of and the judgment paid, it is at least doubtful whether there will be much left for the three-year-old son who inherits the Heinze holdings.

HOUGHTON, MICHIGAN

SANITARY CONDITION OF THE COPPER COUNTRY.—LAKE NAVIGATION AND LOADING ORE.—TRAP-ROCK QUARRIES.—SHAFT-SINKING AT NEGAUNEE.

An inspection of the sanitary conditions of the communities of the copper country by Robert Olesen and Joseph Bolton, of the U. S. Public Health Service, has recently been completed. Almost perfect conditions were found in the mining centres of the district. There is no doubt that the living conditions are far better than in the average mining district. The doctors were considerably pleased with the assistance offered them by the municipal and mining officials.

The close of navigation on the upper Great Lakes is expected in a week or so. Only a few more coal boats are expected at the Marquette docks. Ore shipments have increased during the last month, but the total tonnage from the Lake Superior region will be the lowest since 1911. At some of the mines large stockpiles have been accumulated, but many other mines have little ore on hand. A tonnage record has been established for the new dock of the Lake Superior & Ishpeming railroad at Presque Isle, the upper Marquette harbor. One of the Cleveland-Cliffs Iron Co.'s steamers was loaded with 10,792 tons of ore. This deeper loading was made possible by the new Davis lock recently completed at Sault Ste. Marie.

The Marquette Trap Rock Co. has reopened its quarry at Harvey, and this property and that at the Blemhuber farm are now being worked at full capacity. These are the only two trap-rock quarries in the upper peninsula. The rock at the Blemhuber farm quarry is a massive diorite in the form of a dike. A great deal of the rock taken out at Harvey has been from Keewatin schist. The number of men has been increased at both quarries, and in order to supply the demand for the rock, a full force will be employed at the two quarries through the winter. The demand for the trap-rock from the lower peninsula and Wisconsin has been so great

that next season will probably be the busiest the Company has ever experienced.

The shaft of the Cleveland-Cliffs Iron Co.'s Athens mine, on the Harvey lots at Negaunee, is to be sunk to a depth of over 2000 ft., and is one of the largest projects ever undertaken by an iron-mining company. Joseph Thomas, of the Maas mine, has been placed in charge of the work. Sinking was commenced early in June, and has progressed on an average of about 60 ft. per month. It is expected that within a short time an additional 15 ft. per month can be sunk. Water at the bottom of the shaft has hindered the work, and a small pump has been necessary to keep it from being flooded. The ore on this property probably lies in a 'pitching trough' with a foot-wall of Siamo slate. The inside dimensions of the shaft will be about 17 ft. diameter, with a 3-ft. concrete wall. Three crews, of six men each, work

MAP OF COPPER COUNTRY, MICHIGAN.

on 8-hr. shifts. Thirty-six 5-ft. holes are drilled in the floor of the shaft before a charge of powder is set off. The rock is then hoisted to surface before drilling is again resumed. For one blast, 144 sticks of 80% giant powder are used. The concrete machine mixes and pours 30 cu. yd. of concrete per hour. This is to run into the shaft through a pipe system, and after it is placed in the forms it requires 48 hours to set. When the forms are removed, steel dividing sets for the skip, cage, pipe, and ladder-ways are put in place. It requires 8 hours' work by one crew to remove 10 ft. of forms.

LONDON

RIO TINTO COPPER MINE.—EL ORO MINING & RAILWAY CO.'S AFFAIRS.—TOMBOY MINE.—ZINC, TUNGSTEN, AND LEAD PLANTS.

Like most copper companies, the Rio Tinto of Spain has been hard hit by the war. Not only did Germany take a great deal of the copper, but also large amounts of pyrite, both cupriferous and otherwise. Spanish pyrite has long been the basis of chemical manufacture in Germany. The mines and smelters are at present working half time, and even now the output is slightly greater than the demand. Opportunity is being taken to do an extra amount of development work. No interim dividend is to be paid for the half-year ended June 30. The war is not the only worry to which the Company has been subjected recently. As no doubt readers of the *Press* will remember, the mines were closed during January and part of February owing to a strike, and interruptions from the same cause occurred in March and April. Affairs had been restored to normal, and the output had been raised to record figures when the war supervened.

The directors of the El Oro Mining & Railway Co. report that owing to the disturbed state of Mexico, no accounts have been received from the mine since the end of April. Nor has the manager, A. F. Main, been able to send the usual annual report due at this time. Mr. Main had to suspend all milling and surface work at the end of April, but development has been continued, and the plant and mine have been kept in good order. He reported on August 22 to the effect that the forces of the Constitutionalists entered El Oro on the 7th of that month, after the evacuation of the town by the Federal troops. A levy was made on the mines by the Constitutionalists, and this Company's share was ₱20,000. On September 9, Mr. Main cabled that owing to the difficulty of exporting and disposing of bullion, and to the general unsettled financial conditions in Mexico City, milling could not be resumed. On the 22nd of the same month, he cabled that in view of changed circumstances it would be advisable to resume milling to a limited extent early in October. It is probable that pressure was put on Mr. Main by the Constitutionalists in order to force him to adopt this course. The directors and shareholders of this Company have serious misgivings as to the future.

The Tomboy Gold Mines Co., operating in the Rocky Mountains above Telluride, continues to be a profitable undertaking. This Company has had a romantic and withal a highly creditable career. Formed in 1909 by the Exploration Company to purchase the Tomboy mine, the future appeared to be highly promising, but the orebody gave out two years later, and it was only the sagacity of the late John Herron, the manager, that saved the situation. He took, on his own responsibility, the time available being short, an option on the Argentine property. The purchase price, in cash, was provided during the currency of the option. For 10 years this mine enriched the coffers of the Company. Continuity of interest was then secured by the purchase of the Montana group of claims from the Revenue Tunnel Co., also in the same basin. The Company bought this property for £80,000 cash, all provided out of revenue. This has all been paid, and the dividends have resumed their old level. At the recent meeting of shareholders, Lord Arthur Butler described the present position clearly and concisely. The profit was £81,070, and £62,000 was distributed as dividend, being at the rate of 20%. The annual report appeared in the *Press* of October 31.

The scheme to erect a zinc smelter for the treatment of zinc concentrate from Broken Hill and Burma is likely to be carried out, for the manufacturers of galvanized iron are ready to back it financially. As they are large consumers of zinc, this assures a good market for the output of the smelter. ——Another metallurgical scheme that looks healthy is the extraction of tungsten from wolfram concentrate, from the Shan states, Cornwall, Australia, and Bolivia. The plant is to be erected at Sheffield. In this case also the consumer plays a principal part, for tungsten is used in making tool-steel, and it is the tool manufacturers at Sheffield that are finding the capital for the enterprise.——The plan to erect a lead smelter for Broken Hill concentrate is still in the air, the enthusiasm on the subject having been chilled by the fact that the Port Pirie and Cockle Creek smelters in Australia are now working at full blast, and so are able to take care of the major portion of the Broken Hill output of lead concentrate.

JOPLIN, MISSOURI

REVIVAL OF ACTIVITIES IN THE PORTO RICO DISTRICT.—MILL-BUILDING OPERATIONS IN MISSOURI-OKLAHOMA-KANSAS FIELD.—RECENT DRILL STRIKES.

Two large Texas pumps have been started by George A. Barnett, of Joplin, and Kansas City people on a 17-acre lease of the Van Dorser land at Porto Rico, eight miles northeast of Joplin. More than 3500 gal. of water per minute, pumped from the shaft, is rapidly draining the ground, and mining operations are expected to begin by the latter part of the month. The mine was opened several years ago when zinc ore prices declined suddenly, and before any extensive development could be undertaken, offerings for ore had dropped to such a low level that work could not be conducted at a profit. Following the closing of this property other important mines in the vicinity suspended operations, and for several years this portion of the district has been non-productive. The Vogey mine of the American Zinc, Lead & Smelting Co. is situated near the Barnett property and will probably be placed in operation soon. On another nearby lease, the Carmean & Squires Lead & Zinc Co. operated a 500-ton mill which was destroyed by fire several years ago. This Company has planned to reconstruct this mill, and begin mining operations again when ore prices justify it. The ore encountered in this district occurs in sheet formation, and will yield about 3% blende, and some lead. A formation about 20 ft. thick is encountered at a depth of 160 ft., extending down to 180 feet.

The Twin City Mining Co., a new corporation recently organized, plans to construct a mill of 250-ton daily capacity on a 15-acre lease of the Daugherty & Davey land at Carterville, Missouri, where some extensive prospecting work has been under way for some time. Interested in this Company are John Wingfield, George Moore, Weed Smith, Cleve Bird, William Burns, and Harry Hulett. The lease on which they are operating is near the S. Y. Ramage mine, one of the largest producers of sheet-ore in the district, but no deep mining has been undertaken prior to the operation of the Twin City company. The ore in this mine is not of sheet formation, but is found at a depth of 150 ft.; the ore face is 15 ft. high, and is estimated to yield 15% blende.

A new mill is being constructed by the Cornfield Mining Co. at Miami, Oklahoma. It is one of the few entirely new plants of the district. A number of mills have been constructed which have been made up largely from equipment taken from old plants, but a number of unusual ideas in concentration methods necessitated the use of new equipment throughout at the Cornfield property. The cost of the plant is $17,000. It is being constructed by Frickleton, Onstott & Marcum. The orebody has been opened in three drifts at a depth of 92 to 120 ft., and a second shaft is now being sunk southeast of the original shaft, and a drift is being driven to connect the two and afford better ventilation. A large 'crush-rock heap,' amounting to almost 4000 tons, has been gathering on the surface. The showing of this 'crush pile' is unusually good, both zinc and galena occurring in exceptional richness. The operators claim to have a large body of equally good ore blocked out in the drifts, and in several drill-holes on the lease.

The long drawn out period of low zinc-ore prices has resulted in some of the larger mines of the district being closed, and many men thrown out of employment. Considerable shallow prospecting on the part of idle wage earners has followed, and some good discoveries of shallow galena have been made in various parts of the district. In an area northeast of Duenweg, Missouri, where little work has been under way for several years, three different companies are now at work on the Bonni Patti land, and all are producing a good tonnage of galena from a depth of about 80 ft.——Another group of good lead prospects is being opened immediately south of Joplin.——A company on the Boruff land is making as high as 40,000 lb. of galena each week over hand-jigs, with only two men working in the ground.——Fay & Burnett are prospecting on the Paul estate, also south of Joplin, and have opened rich lead ore at a depth of 80 ft. In sinking three feet in a new shaft they took out 3000 lb. of galena.

Two Joplin newspaper men have recently done well from mines near this city. One is Ray Cochran, managing editor of the *Joplin Daily Globe*, who owns a half interest in the Flynn & Cochran mine on the Hornaday lease of the Connor land at Central City, west of Joplin. Good calamine and galena have been encountered. The partners went into an old shaft and spent less than $150 each in placing the mine on a productive basis. They are now clearing about $200 per week each, and the outlook for continued production is good. The other newspaper man is John Powers, proof reader on the *Globe*. He has taken over the old Little Jew mine, west of Joplin, has repaired the mill and opened a rich face at a depth of 150 ft. Scarcity of water at this mine caused former operators to suspend work. At one time water was obtained from another mine half a mile distant, but when work was suspended at the other property the water famine at the Little Jew was again in evidence. Powers has overcome this difficulty by laying 3000 ft. of pipe to connect with the city water mains.

CHIHUAHUA, MEXICO

SUMMARY OF CONDITIONS IN THIS DISTRICT, LABOR, CYANIDE, AND SMELTERS.—RIO TINTO, EL CRISTO, CUSI, CUSI CONSOLIDATED, EL POTOSI, AND JUSTICIA COMPANIES.—INTERESTS IN NICARAGUA.

In spite of difficulties in transportation, and higher prices of supplies, mining can be carried on here now cheaper than in normal times, owing to the fact that wages and freight rates have not advanced in proportion to the drop in the gold value of the current money.——It is generally thought that there is little danger of interference with business or movement of ores and supplies in the near future, on account of fighting between the different factions, no matter what may happen in other parts of the country. There is a great scarcity of labor for all purposes, chiefly owing to the continued recruiting of all available men into the army. It is expected that as soon as order is restored in the country there will be plenty of labor to operate the mines and smelters at normal capacity. There is no lack of ore, but not sufficient men to mine and smelt it, and a shortage of transportation facilities to move it to market. On the whole, the outlook for mining here, while not exactly bright, is more cheerful than for a long time.

The cyanide problem has not yet become acute, as most of the mines using it were well stocked when the war broke out, and can keep going for some time on their present supplies.

The Chihuahua plant of the American Smelting & Refining Co. is working steadily, but cannot secure sufficient men to operate all the furnaces, so only four are running at present. All shippers to the local smelter are restricted in their tonnage, and many are unable to ship at all, owing to the inability of the smelter to handle all the ore offered.

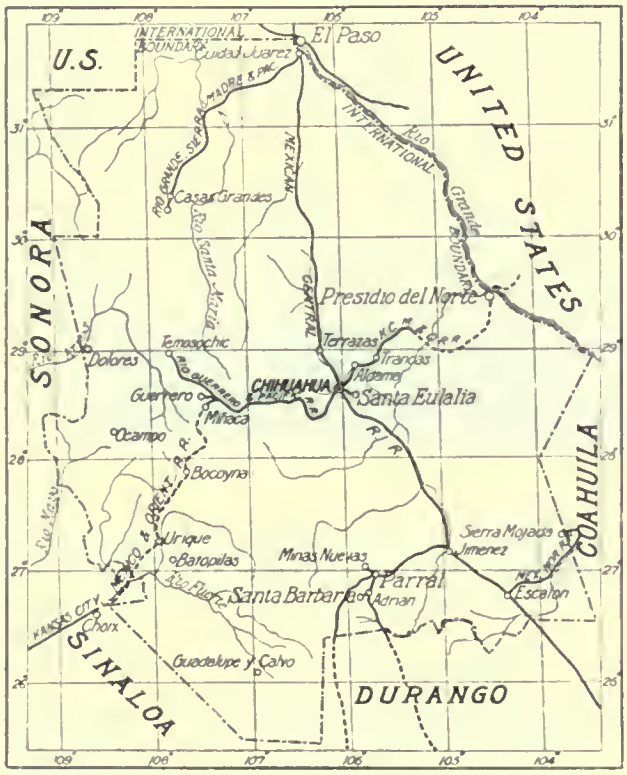
The smelter of the Cia. Metalurgica de Torreon, at Torreon, is again receiving ore, as is also the Azarco plant of the A. S. & R. company. The smelter of the Peñoles company, at Mapimi, Durango, is also reported to be about to resume. This will relieve the situation somewhat, and allow many mines to resume shipments.

The Rio Tinto Copper Co., at Terrazas, is sinking the main shaft to further develop the great body of ore in that part of the property. The smelter is idle, owing to lack of labor.

El Cristo Mining Co., working the property of that name at Santa Eulalia, is again shipping to the Chihuahua smelter. ——J. T. McClammy and associates have secured an option on the Dolores mine in that district and are about to commence work under the supervision of W. A. Fritsche. This mine has a famous record as a producer, but has been idle for some years on account of litigation.——Schuyler Lawrence, leasing the San Antonio mine of the A. S. & R. company, has resumed shipments of lead ore to the smelter.

At Cusihuiriachic, the Cusi Mining Co. is working with a reduced force, and shipping a restricted tonnage to the smelter.——The Cusi Consolidated Mining Co. is working chiefly at development, but is extracting some good-grade gold and silver ore in the course of that work.

Zinc mining is again showing signs of activity after lying dormant for a long time.——El Potosi Mining Co. has lately



MAP OF STATE OF CHIHUAHUA.

made a contract in the United States for a large tonnage of calamine ore, and other producers are expecting to ship soon.

A company under the management of S. G. Burn has taken an option and lease on the Justicia copper mine at Chorreros, east of this city, and will commence operations as soon as the Orient railway is repaired to Falonier, so that the ore can be moved to the smelter. The Justicia has been a large producer of high-grade ore and concentrate, and will doubtless again ship heavily as soon as conditions permit, as the ore-bodies are not yet fully opened.

A syndicate has been formed in Chihuahua to conduct mining exploration and development in Nicaragua, with R. H. Burrows in charge of its affairs in the field. He has already left for that country.

While conditions are not normal, there has been a decided improvement within the past six months, and the outlook for Chihuahua mines is a great deal brighter than it has been for some time. Peace has been established in the state and is being preserved by the Constitutionalist authorities; law and order are being kept and mining operations where being conducted are proceeding uninterruptedly.

SILVER CITY, NEW MEXICO

IRON-ORE MINING IN GRANT COUNTY.—EMPIRE ZINC CO.'S OPERATIONS.—SIERRA COUNTY ACTIVITIES.

Practically all the iron ore produced in New Mexico during 1913 came from the Brockman and Penrose estates mines at Fierro, Grant county, there being only 16,583 long tons from other sources. Approximately 90,000 tons of magnetite was mined from the Snow Flake and 58,000 tons from the Jim Fair by the Colorado Fuel & Iron Co., and shipped to its works at Pueblo, Colorado. The state stands eleventh in rank with the other states, against seventh place for 1912. The shortage of 100,000 tons in 1913 was doubtless due to the curtailment of shipments to Colorado on account of the labor trouble there. Many new iron operators are in the field this year, and the output in 1914 will no doubt eclipse those of the preceding three years. The Yellow Jacket iron mines at White Oaks, Lincoln county, have been put in shape for the economic extraction of ore by Swoyer & Evans, and occasional shipments to Pueblo are being made. In the Hanover and Fierro districts, contracts are being let for magnetite of 50% and over, delivered on cars. The C. F. & I. company is at present extracting about 300 tons per day from the Snow Flake open-cut and immediate claims, the Jim Fair being held in reserve. Since Phelps, Dodge & Co. pulled pumps and abandoned its copper properties at Fierro, the Colorado people are the only active operators in the district.

Below Fierro, the Empire Zinc Co. is preparing for the development of its zinc sulphide claims on Thunderbolt hill, and a tramway is being constructed. Shipments of carbonate ore from the Company's workings known as the Nason tunnel, are being made over a new tramway. Shaft sinking is in progress at the mines. The Copper Queen mine, between Hanover and Fierro, has been purchased by the Company for its water supply, and will be used if a sufficient quantity of water cannot be found near the site of a proposed power-plant and concentrator. A one-mile pipe-line will deliver water from the Copper Queen to Empire Zinc workings.——In the same district, McKenna & Gerhardt are developing the Mountain Home mines in Humboldt mountain. They recently shipped a car of copper ore to El Paso taken from a small deposit or pocket.

Several new operators have entered the Pinos Altos field of Grant county, among whom are Holman and Hickman of Santa Rita, who purpose working the Young properties.—— The Mountain Key, Jr., Mining Co. is being organized to take over several promising mines, and the Silver Hill operators are incorporating prior to commencing development in the upper levels.——La Fortuna mine is being worked by Norris and Spitzley, and driving has cut two rich veins, extensions from the main vein system of the area. The ore is rich in lead and silver. A custom mill is under consideration in the district.

In Sierra county, the Bi-Metallic company, at Sierra Blanca, has received a consignment of drills, an air-compressor, and other machinery.——The Amethyst mine at Kingston is being opened again. The Overlook mine in the same camp recently made a large shipment of silver ore.——Owen Bros., of Santa Rita, have taken over the Tom Casey properties in the Trujillo district, and are contemplating development.——The Ready Pay group at Hillsboro was examined a short time ago by a representative of Eastern investors.——Clyde M. Becker and associates have cut two promising veins in driving 60 ft. in a shallow shaft near Rincon. Property owners near by are consolidating claims and intend forming a company.— It is reported that a manganese mine will be developed owing to the demand for the mineral.

The old Jerry Hoyle mine near Lordsburg, abandoned for 30 years, is being reopened by P. Wehner.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

'Mineral Resources of Alaska' is the title of *Bulletin* 592, by Alfred H. Brooks and others, published by the U. S. Geological Survey. It consists of 413 pages, with illustrations, maps, plans, and a bibliography on recent Survey publications on the territory. This volume is a report on progress of investigations in 1913. Contents are as follows: preface, administrative report, the mineral deposits of Alaska, the Chisana placer district, and the Alaska mining industry in 1913, by A. H. Brooks; lode mining in the Ketchikan region, by P. S. Smith; marble resources of the Juneau, Skagway, and Sitka districts, and a barite deposit near Wrangell, by E. F. Burchard; mineral deposits of the Yakataga district, by A. G. Maddren; preliminary report on a water-power reconnaissance in south-central Alaska, by C. E. Ellsworth and R. W. Davenport; the Port Wells gold-lode district, and mining on Prince William sound, by B. L. Johnson; gold lodes and placers of the Willow Creek district, by S. R. Capps; mineral resources of the upper Matanuska and Nelchina valleys, by G. C. Martin and J. B. Mertie, Jr.; preliminary report on the Broad Pass region, and mining in the Valdez Creek placer district, by F. H. Moffit; lode mining near Fairbanks, and placer mining in the Yukon-Tanana region, by Theodore Chapin; placer mining in the Ruby district, and mineral resources of the Yukon-Koyukuk region, by H. M. Eakin; and placer mining on Seward peninsula, and lode developments on Seward peninsula, by Theodore Chapin.

ITIDAROD, ALASKA.

Cordova

According to A. J. Elliott, secretary, and Louis G. Hinckle, superintendent of the Hubbard-Elliott Copper Co., development at the mine in the Kukalina district is very satisfactory. In the 1000-ft. adit rich bornite and chalcopyrite were cut at a vertical depth of 150 ft., 300 ft. in from the portal. This has been opened for 170 ft. On October 17, at a depth of 400 ft., 30 ft. of chalcopyrite was also cut. A concentrator, electric power-plant, compressors, and possibly a nine-mile tramway connecting the Company's property with the C. R. & N. W. railway, at Mile 144 is proposed next season. Work will be resumed as early as possible, it being the intention of the Company to commence freighting in additional equipment and supplies early in January 1915. The head office is in Chicago.

Iditarod

An accumulation of mail, amounting to nearly 100 sacks, is lying at the Seward post-office for Iditarod.

Knik

Navigation to Knik is closed until next April.

ARIZONA

Gila County

The proposal to divide this county, and form another under the name of Miami county, which, though small, would include most of the mining centres, was defeated at the elections on November 3.

The Iron Cap Copper Co. closed its mine on November 1, on account of the copper market. The mine is dry, and there is about 400 ft. of good ore in the stopes. The plant is in good condition for resumption at any time.

A promising gold-bearing area is said to be in the Chemehuevis district, 14 miles south of Franconia, on the Santa Fe railroad. At the Yellow Jacket is 10 to 36 in. of $18 ore, 14 ft. of $37 to $40 ore in the Los Angeles, and 12 ft. of $18 to $20 ore in the Constitution. A zinc-lead-gold deposit is being worked by M. R. Ruiz.

Yavapai County

The Great Belcher mine and other claims are being reworked by El Paso people. A shaft was formerly sunk to 800 ft., and at 300 ft. a wide vein was cut. Lack of capital resulted in a shut-down. The Red Rock was opened to 300 ft. Dumps on these claims amount to about 25,000 tons of profitable gold ore. The Poland branch of the Bradshaw Mountain railroad runs across the property, and the Big Bug creek flows nearby. A 10-stamp mill is on the Red Rock, and will be used to crush ore. Under certain conditions the new owners are to pay $50,000 for the mines.——The Poland mill recently crushed 168 tons of ore from the Poorman mine. Good ore is being opened in the Bonanza or Harqua Hala mine.——The Stoddard Copper Co. is getting good results at its mine.——The Lynx Creek Mining Co. is preparing to work its placer ground.

CALIFORNIA

Butte County

The Supreme Court has upheld the previous decision of a judge and jury in a case wherein Lavinia Crabbe sued the Mammoth Channel Gold Mining Co. for damages for her husband's death. The verdict was for $20,000.

Two boats of the Oroville Dredging Co. recovered $4090 during the week ended October 1.

Modoc County

It is said that the Big Four mine at High Grade has been optioned to the Tonopah-Belmont company of Nevada, whose engineers have been examining it for some time.——Some rich ore has been opened in the Modoc mine, owned by the

Wrigley people of Chicago. Work will be continued during the winter.

SACRAMENTO COUNTY

The Natomas Consolidated company has started the Union dredge in the Blue Ravine district, near Folsom. This boat was shut down over a year ago by the former owners.

SHASTA COUNTY

Six feet of good ore is being opened in the American mine at French gulch. F. L. Sullivan is in charge.——Van Ness Bros. are prospecting at their Five Pines claim.——The Mammoth Copper Co.'s output in October was estimated at 1,200,000 pounds.

The Noble Electric Steel Co. will increase its capital from 100,000 $10 shares to 100,000 common at $10 and 50,000 preferred at $10 each. The latter stock will receive out of surplus profits a cumulative dividend at the rate of 8% per year, on the par value dating from the original issue. This stock will be non-assessable.

SIERRA COUNTY

The Tightner mill is working steadily on good ore. Retimbering of parts of the mine is under way. The Red Star claim is being developed by a cross-cut from the Tightner workings, and good results are expected.——The Red Ledge mine on Kansas creek, and operated by the Bank Mining & Promotion Co., of Buffalo, was recently inspected by W. H. Barnhardt. A good deal of new work is contemplated. John B. Moulton is superintendent.——As soon as the new pump is installed, sinking of the Telegraph shaft, near Downieville, will be continued.——At the Alhambra the Sears roller quartz mill is working 16 hours per day. A fair tonnage of ore is ready for crushing.—Development is under way at the Mount Alta, Gold Bluff-Oxford, Monte Cristo, City of Six, Mott tunnel, and Little North Fork properties.

TRINITY COUNTY

At the Enterprise mine, near Helena, a large tonnage of $20 ore has been opened. Repairs are being made to the water-power plant and the 10-stamp mill. R. A. Skinner is manager.——A lower adit is being driven at the Oversight. ——In the upper level some good ore has been exposed. A. H. Wolfe is managing owner.

COLORADO

The annual report of the Colorado Fuel & Iron Co. shows that gross earnings totaled $17,803,025, a decrease of $6,512,862 compared with 1912. Net earnings totaled $1,073,769, a reduction of $2,546,496. The decreases were due to labor troubles in the fuel, and general curtailment in the steel business. The Company operates iron mines in New Mexico and coal mines and iron works in Colorado.

Gold worth $25,000,000 was shipped from Denver to New York last week, the largest single consignment ever made in the country.

GILPIN COUNTY

Companies and lessees made a large number of shipments of milling and smelting ores from the Black Hawk district last week.——The Bates Leasing Co. shipped 12.5 and 13.2 tons of gold-silver concentrate, worth $24.62 and $38.34 per ton, respectively, from the Stroehle mill to the Globe smelter. Twenty tons of smelting ore averaged 2.62 oz. gold and 18.4 oz. silver per ton.——Lessees at the Lake mine, near the boundary of Gilpin and Clear Creek counties, produced over 1000 tons of concentrating and smelting ore in October. The property is worked through the Big Five adit, above Idaho Springs.

LAKE COUNTY (LEADVILLE)

The first shipment of zinc oxide has been made from the local zinc smelter.——As soon as the Colorado Power Co. has finished its line, the Penrose shaft will be overhauled.

PITKIN COUNTY

The fire in the lower workings of the Smuggler mine still baffles all efforts to put it out. No serious accidents have happened to the men employed. A rescue-car has been at the property.

TELLER COUNTY (CRIPPLE CREEK)

The committee in charge of work at the Roosevelt drainage tunnel reports that the flow of water is 432,000,000 gal. per month. In October the adit was extended 185 ft. with one shift drilling and one tramming. Two shifts are now to be employed.

The shaft-house and other buildings, with all the machinery, at the El Paso mine, were destroyed by fire early on November 5. The loss is estimated at $150,000. But for the heroic work of the engineer at the hoist, James Herring, and other men and officials, about 15 men would have been trapped in the mine. Work will be slightly curtailed, and the plant rebuilt.

SURFACE PLANT AT EL PASO MINE.

Seven sets of sub-lessees are working and producing good ore from the Vindicator No. 2, under Potts and Starkweather. Martin & Co. sent out $27 ore last week.

IDAHO

SHOSHONE COUNTY

According to the state mine inspector, Robert N. Bell, the mining industry of northern Idaho is marking time at present, on account of the metal markets. The lead output is being made at a loss of 50c. per 100 lb., the silver contained making good this deficiency. The Bunker Hill & Sullivan company will continue at normal capacity as long as the smelters will receive the concentrate. New development, in the district covered by the recent trip of the inspector, shows a good increase in ore reserves in the deep levels of the principal mines at Burke.

In the Nine-Mile district, the Tamarack and Custer, Success, and Interstate-Callahan have made good, and are suffering from curtailment owing to a poor market for zinc, and small milling capacity.

The flotation process at the Interstate, devised by D. F. Haley and L. F. Fogel, is a complete success, and is recovering 90% of the lead and 70% of the zinc in the ore treated. The system is inexpensive. Losses have been mainly in slime at this mill. A small quantity of oil is added to the pulp before it enters the suction of a centrifugal pump, and the whole is well mixed. The discharge of the pump is through a ¾-in. pipe, and is delivered into a 6-in. pipe slightly above a V-shaped box 4 ft. long. A froth overflows, remaining on top of the solution in the box, and is then removed by overflow or scraping. The general mill extraction has been improved 10% by this simple device.

In the Kellogg-Wardner district, the Bunker Hill & Sullivan, Last Chance, Sierra Nevada, Ontario, and Stewart mines are

giving satisfactory returns, considering the conditions of the markets; while the Caledonia is making more money per man employed than any other mine ever did in the history of the county.

Experiments at the Bunker Hill & Sullivan, according to the president, F. W. Bradley, show that it may prove unnecessary to ship concentrate to smelters in the future. The Malm process, an electro-chemical one, is under development.

WALLACE, IDAHO.

MONTANA

Silverbow County

The North Butte Mining Co. reports as follows for the third quarter of 1914: Early in August the working force was reduced to 50% capacity, and the last week in that month, and three weeks in September, all mining was stopped for retimbering 325 ft. of the Speculator shaft. Late in September work was resumed on a 50% basis. The regular quarterly dividend was passed on account of the copper market.

Development amounted to 1775 ft., and ore reserves decreased slightly owing to the irregular size and value of the Edith may vein at 2200 and 2600 ft., also on account of the shut-down. Driving was done on the 2200, 2400, 2600, and 2800-ft. levels on this vein. At the latter depth the east drift shows 133 ft. of ore 6 ft. wide, assaying 4% copper and 2.5 oz. silver per ton. The west drift was extended 97 ft., of which 80 ft. was 4 ft. wide, containing 6% copper and 5 oz. silver. Some 'bunches' of high-grade ore were cut at 2600 ft. on the Jessie vein. Good ore was further opened at 2200, 2400, and 2600 ft. on the Snowball vein.

Ore treated amounted to 66,035 tons and 18½ tons of precipitates, yielding 3,337,023 lb. copper, 201,049 oz. silver, and 221 oz. gold. Assets include cash, $111,546; and copper and silver on hand, $1,077,868; liabilities include advances in metals, $685,327; and surplus, $2,883,149.

Eleven out of the twenty-two shafts of the Anaconda company are working, and the smelting operations at Anaconda are correspondingly curtailed. The plant at Great Falls is entirely closed down, including the refinery.

NEVADA

Clark County

(Special Correspondence.)—A 60-ton cyanide plant is to be supplied by the Stearns-Roger Manufacturing Co., of Denver, and erected by J. H. Alpenfels, at the Flagstaff group of mines, developed by the Nevada-Eldorado Mines Co. in Eldorado cañon. The mill will consist of stamps, a tube-mill, Dorr system of agitation and thickening, and an Oliver filter. The property is now owned by the Colorado-Nevada Mining & Milling Company.

Nelson, November 4.

Esmeralda County

The Goldfield Consolidated Mines Co. reports as follows for the quarter ended September 30:

Ore treated, tons	79,605
Gold recovered	$918,088
Expenditure	516,878
Net profit	401,210

Since the last report, the sum of $374,211 has been paid to complete purchase of control of the Aurora Consolidated Mines Co. Cash and bills receivable on October 31 totaled $697,000. No dividend will be paid for the third quarter.

The hoist-house, compressor building, blacksmith-shop, transformer plant, electric motors, and equipment worth $6000 was burned on November 4. The steel head-frame was uninjured. The plant is to be replaced at once. Charles D. Wilkinson is general manager.

Humboldt County

Seven feet of $50 ore has been cut in a rise from the 400-ft. level of the Big Four lease at Rochester. Foundations for the new mill are finished.——Fourteen men are working at the Nevada Packard mine. A carload of ore last week assayed 230 oz. silver and $2.50 gold per ton. Frank Margrave is superintendent.——The Kramer-Hampton lease produced 135 tons of $65 ore in October. These properties are improving steadily.

The Seven Troughs Coalition mine and mill were described in the *Review-Miner* of Lovelocks on October 30. Most of the underground work is being done on the rich ore at 1200 ft. The 10-stamp mill is now producing about $2000 per day.——The Mazuma Ore Reduction Co., in charge of F. R. Lockhardt, has acquired the Darby mill at Mazuma. It is a modern plant and will receive custom ore for treatment at a moderate charge.

Mineral County

There are about 100 men working in the mines and three mills of Rawhide. The principal producers are the Nevada New Mines Co., Rawhide Coalition, and Rawhide Queen, and the Black Eagle Mining & Milling Co.——There are 150 men employed at the Aurora mine and mill. A recent shipment of bullion was valued at $30,000.

Nye County

(Special Correspondence.)—A carload of gold-silver-lead ore is being shipped by J. Gallagher from his lease in Camp cañon, near Blue Eagle ranch at Railroad Valley. The ore is said to assay $90 per ton.——It is reported that Irwin Bros. have sold their mine near Railroad Valley to Tonopah people for $50,000. A two-stamp Campbell & Kelly mill has been crushing ore with good results for some time.

Ely, White Pine county, November 2.

Tonopah mines produced 10,193 tons of ore, worth $199,434, last week.——In the Belmont, a rise above the 900-ft. level shows 2 ft. of rich ore. The final clean-up for October resulted in 179,014 oz. bullion.

At Tonogold, the shaft at the Lone Hand lease No. 2 is down 41 ft., showing 'bunches' of ore with free gold.——The Gingles shaft is down 51 ft., and will be continued to 100 ft. ——Murphy and Co.'s shaft has followed good ore to 70 ft. ——Twelve inches of 'sugar' quartz, with free gold, has been opened in the Wardle-Burnham lease.——The *Tonopah Miner* lease shaft has cut some stringers at 40 ft.——Other claims are being actively worked.

White Pine County

(Special Correspondence.)—Wherever possible, the Nevada Consolidated company is reducing costs. Good results are being obtained from the oil agitators which are made in the Company's foundry. It is said that they will be installed in one of the units of the mill.——A carload of gold-silver-lead ore was recently shipped by Rowley and Ferguson from their lease on the Hayes claim, near the old Coppermines claim, near Star Pointer. The ore netted about $20 per ton. F. Smith has secured a lease on part of the Hayes. Both parties are working oxidized ore near the surface.

Ely, November 2.

TEXAS

Burnet County

(Special Correspondence.)—What is said to be the only known deposit of ichthyol (a sulphonated hydrocarbon of syrupy consistence) in the United States underlays a tract of 500 acres of land near Burnet. The property has been purchased by a syndicate of New York men, headed by William Polatsik, an industrial chemist, who has arrived here for the purpose of mining the mineral on an extensive scale. Mr. Polatsik says that the world's supply of ichthyol has heretofore come from a certain district in the Austrian Tyrol, and that the shutting off of those mines by the war in Europe led to an investigation of the possibilities of the product being obtained somewhere in this country. It was found that the State Geological Survey of Texas gave an account of the existence of ichthyol near Burnet. Mr. Polatsik came here, and his explorations convinced him that the deposit is probably the largest and richest in the world. One of its peculiarities is that it is soluble in water, alcohol, or oil. It resembles carbolic acid in its effects, being a mild antiseptic. It is known also as ammonia ichtho sulphonate. It is used for a variety of purposes and commands a good price. Mr. Polatsik has awarded the contracts for the construction of the necessary plant to crush the rock and extract the substance. Mining will be started on an extensive scale in a short time.

Burnet, October 24.

UTAH

Beaver County

The Newton district shows considerable activity. Owners of the Sheep Rock property are going to test their ground thoroughly.——In the Star district, work has been curtailed at the Monitor, owing to the low price of lead and silver.

Juab County

The Utah Minerals Concentrating Co.'s 100-ton plant to treat ore from the Chief Consolidated dump is finished, being constructed in 60 days. It consists of a gyratory crusher, rolls, tube-mills, and concentrators.——The station at 1700 ft. in the Eagle & Blue Bell is practically finished. Weekly shipments of silver-lead ore from this mine total 15 cars.——Sixteen mines in the Tintic district sent out 134 cars last week.

Salt Lake County

The Utah Copper Co.'s third quarterly report shows the following results: Owing to the effect of the war on copper, the mine was reduced to 50% capacity on August 6, and the Arthur mill was closed on the following day, since which time the Magna has treated the ore extracted.

Details of results.	Third quarter of 1913.	Third quarter of 1912.
Overburden removed, cubic yards	1,408,224	1,824,997
Ore treated, tons	1,466,606	2,006,157
Average copper content, per cent	1.4356	1.4573
Recovery, per cent	68.13	68.44
Metal production, pounds	28,686,672	40,017,562
Cost of production, cents per pound	7.760	7.539
Net profit from all sources	$1,312,738	$2,819,104
Dividends paid	$1,218,367	$1,201,710
Copper on hand, pounds	50,118,797	46,704,098

No income was derived from dividends of the Nevada Consolidated Copper Co., this being $375,187 in the previous quarter.

Lessees at the Wasatch mine at Alta have shipped 37 tons of ore assaying 0.012 oz. gold, 61.3 oz. silver, 6.7% lead, 11.65% copper, 10.7% zinc, and 14.5% iron. It returned $1346.

Summit County

The Snake Creek tunnel was driven 328 ft. in October, and is now in a total of 9764 ft. Low air pressure and hard ground interfered with a larger footage.

The Daly-Judge mine is in good condition, and in the mill the Callow flotation process is working well.——The dispute between the shareholders in the Silver King Consolidated and the president, Solon Spiro, is still being discussed.——A small Holt-Dern furnace is being tested at the Park City mills plant. A Christiernsen furnace is already at work. The Mines Operating Co. has a 10-ton Holt-Dern roaster giving good results.

WASHINGTON

Chelan County

The Wenatchee Gold Mining Co. held its annual meeting at Wenatchee recently. Charles F. Pleiffer is in charge of the property on the Entiat river. An 800-ft. adit is to be started to cut the vein at a lower level. The output during the past two years has been $75,000, of which $14,000 was paid in dividends.

CANADA

Ontario

At Cobalt, the Temiskaming & Hudson Bay company paid a dividend of 300%, equal to $23,283, on November 10. The total since 1905 is 25,000%, or $1,940,250.——Hydraulicking on the surface of the Nipissing has exposed from 2 to 6 in. of rich ore for about 150 ft.——Another scheme for reorganizing the Hailey company is being prepared. Ore reserves are estimated to contain 400,000 oz. silver.——The Right of Way Mines Co. has declared a dividend of 1%, equal to $16,865, the first since 1911. The total to date is 78%, or $543,754, on a capital of $1,685,500.

At Porcupine, the second unit of the new compressor plant of the Hollinger is at work. It has a capacity of 45 drills. Twenty additional stamps are being erected, mainly to crush ore from the Acme mine. The plant is now treating 700 tons per day, but by next spring this will probably be about 1300 tons.

KOREA

The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports the following results for October:

Stamps working	10
Time, days	28
Ore crushed, tons	6,126
Total recovery	$59,000

Operating expenses	25,000
Net earnings	34,000

The Oriental Consolidated Mining Co.'s October outpnt was valued at $135,157. In September the mills and cyanide plants treated 25.633 tons of ore for $132,201. The Taracol plant made a recovery of 96%. The Kuk San Dong plant finished its dump on September 25, and is to be reërected at the Maibong mill to treat concentrate. The rainy season is over, the total for the year to date being 83 in. The Candlestick mine is short of men.

MEXICO

A decree was pnblished last July fixing a tax of 60 *centavos* per ton on crude petroleum prodnced in the republic, and has again been published in *El Constitucionalista* by order of Vennstiano Carranza.

Mexico City is in the throes of a milk and toothpick famine, while sugar and salt are at a high figure. The quality of the bread made is being complained of.

Puebla

Large forces of Constitutionalist troops are being mobilized in this state to attack ex-Federal generals and their troops.

NICARAGUA

The Panama Mining Co., of Philadelphia, Pennsylvania, has issued a circular in which it states that its property in Nicaragua has been optioned to the Tonopah Mining Co. of Nevada until Jannary 31, 1915, for $50,000. Of this, $30,000 has been paid. If the deal is concluded, an additional sum of $45,000 will be paid to the Panama company, which has debts approximating $70,000. The permanent interest of Panama stockholders nnder this agreement will amount to 400,000 shares in a company incorporated for $1,000,000, par $1 per share, which will then be immediately exchangeable for Panama Mining Co. stock, in the ratio of 40 shares stock of the new company to be organized by the Tonopah Mining Co. for 100 shares of Panama stock.

PERU

Since the gold standard was put into effect in this country in 1898, the mint has coined £1,621,117 in gold. Imports and exports since that date are £3,916,787 and £367,144, respectively, leaving a net influx of £3,549,643, which, added to the amount coined, gives an approximate circulation of £5,170,760.

The Cerro de Pasco company's hydro-electric plant at Oroya is in full operation, supplying power for the mines and smelter.

PHILIPPINE ISLANDS

The third clean-up of the Gumaos Placer Co. has produced 537 oz. of gold, which together with previous yields of 604 and 867 oz. makes a total of 2008 oz. for August, valued at ₱73,284. The dredge worked for 517 hours and handled 82,000 cu. yd. of gravel.

The Mackay School of Mines of the University of Nevada, at Reno, which gives instruction to men for mines, mills, and smelters, etc., and makes assays free of charge for Nevada prospectors, has decided to start a four weeks' course in prospecting in February 1915. There will be no fee for instruction, only $5 to cover partly actual cost of supplies used during the period. There will be nine lectures on excavation of earth and rock, nine on prospecting, eight laboratory exercises on mineralogy, ten lectures on geology of mineral deposits, four on assaying, eight laboratory exercises on assaying, four on gas-engines, six laboratory exercises on first-aid to the injured, and four lectures on mining law.

The American Road Builders' Association will hold a congress in Chicago on December 14 to 18. A number of papers have already been received.

PERSONAL

C. M. Weld has gone to Cuba.

Alfred Hunt is down from Juneau.

W. DeL. Benedict is on his way to California.

Sumner S. Smith has gone to Washington, D. C.

Karl E. Eilers was in San Francisco last week.

F. G. Cottrell has gone to Salt Lake City and Butte.

F. Sommer Schmidt is in charge at the American Flag mine, Park City, Utah.

Carr B. Neal is in San Francisco, having come from New York by way of Panama.

F. W. Bradley reached San Francisco last week. He will go to New York November 23.

Robert H. Richards will spend the month of November in Virginia on professional work.

F. Lynwood Garrison sailed for San Domingo on November 5 and expects to return about Christmas time.

Ellard W. Carson, of Los Angeles, has been appointed general manager for the Cambria Quicksilver Company.

Walter Harvey Weed is spending a week in New York before leaving for an extended trip to Montana, Nevada, Idaho, and Arizona.

George E. Roberts will be assistant to the president of the National City bank and not president as erroneously announced last week.

W. R. Ingalls has declined reëlection as secretary of the Mining and Metallurgical Society after four years of distinguished and exacting service.

G. Cleveland Taylor, of Republic, Washington, has taken over the assay office formerly owned by F. W. Bewley and will conduct a custom assay office in connection with general engineering.

Obituary

F. Augustus Heinze, who died at Saratoga, New York, November 4, was a man whose striking career in mining is widely known. Born in Brooklyn, New York, of German-American parents in 1869, he was educated at the Polytechnic Institute, Columbia School of Mines, and in Germany. When he went to Montana in 1889 he was possessed, not only of much natural ability and great energy, but the best technical knowledge then available. Unfortunately, he chose to use these advantages in a way that brought him into prompt and sharp controversy with fellow mining men and which ultimately led to his financial ruin. Heinze recognized quickly that the defects of the American mining law and the unsettled and somewhat crude condition of law enforcement in Montana at the time, left many weak points in the titles of his neighbors. Selecting claims for their strategic value, a maneuver which he was by no means the first or the last to adopt, he plunged Butte into a maze of litigation mixed with politics which became a reproach to the whole nation and industry. Heinze was by no means solely to blame for this—responsibility must be assessed widely—but when through the good offices of Thomas F. Cole and J. D. Ryan he was eliminated by purchase of his holdings, a welcome peace came to the war-weary district. From Butte, Heinze went to New York, where he lost in Wall street much of the money he had won at Butte, but in Ontario, Utah, Idaho, and elsewhere he retained important holdings to the time of his death. He was a hard fighter and he had to meet the same sort of fighting that he put up. His picturesque career leaves a feeling of regret that such energy and ability should have been used to so little good purpose.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, November 12.

Antimony	15	—15¼
Electrolytic copper	13	—13¼
Pig lead	3.85	—4.80
Quicksilver (flask)	$55	
Tin	36	—37½
Spelter	6½	—6¾
Zinc dust, 100-kg. zinc-lined cases	10	

EASTERN METAL MARKET

The New York Metal Exchange reported the following prices on November 11: spot tin, easy, five-ton lots, 33.87½ to 34.25c.; and 25-ton lots, 33.75 to 34.37½c.; lead, 3.50 to 3.60c.; spelter, 4.90 to 5c.; electrolytic copper, 11.37½ to 11.50c.; and Lake, 11.50 to 11.75c. for 30 days. The demand for copper, especially from domestic consumers, is improving.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

The upward movement shown at the end of last week has received a check, and prices are weaker, as follows: 49⅞, 49⅝, 49⅜, and 49c. at New York, and 23, 22⅞, 22¾, and 22⅝d. per ounce in London. It is probable that now the German cruiser 'Emden' is out of the way, more silver will be sent to India.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending

May	15.42	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

Total exports in October were about 55,000,000 lb. Statistics of exports of copper are now withheld by the government for 30 days, so November figures will not be available until December. The visible supply in England, France, and afloat thereto was 29,671 tons on October 1, and increased 1772 tons during the month. Supplies at Rotterdam increased 200 tons. London quotations are £59 10s. per ton, and New York 11.25 to 11.50c. per pound. The Anaconda company's October output was 11,800,000 lb., against 12,400,000 lb. in September.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Oct.	15 55.00	Oct.	29 50.00

May	49.10	33.29	Nov.	39.77	....
June	45.10	30.72	Dec.	37.57	....

Spot stocks of tin are scarce in New York, and prices have risen to 34.25c. per pound. Straits tin in London is £139 per ton.

CYANIDE

It is reported that the steamer 'Sun,' which was captured by the British authorities, and was to have brought a cargo of cyanide from Rotterdam, as mentioned in this journal of October 31, has been released. It has been loaded with 1000 tons of cyanide and is on its way to New York from Rotterdam. Arrangements are being made for direct shipments of the salt from Copenhagen to San Francisco.

ALUMINUM

Throughout October there was little or no variance from the quotation of 18 to 18.50c. for 98 to 99% pure aluminum, in wholesale lots, smaller quantities commanding a premium as usual. About the middle of the month there was a slight spurt in demand, but it was not generally felt.

Gold and silver bullion received at the San Francisco mint in October amounted to 524,630.80 oz., and 82,649.63 oz., respectively, worth $6,755,637.69. Coinage executed amounted to $5,026,000. Coin, bullion, etc., on hand at the end of the month totaled $254,510,446. Transactions at the New York Assay Office were $7,342,042, compared with $4,162,009 in September.

COMPANY REPORTS

NORTH BROKEN HILL, LIMITED

This is one of the 'Barrier' companies of New South Wales, and the report covers the first half of 1914. A total of 156,020 tons of ore was concentrated, yielding 27,550 tons of concentrate assaying 70% lead and 23.6 oz. silver. There was sold to the Amalgamated company (flotation works) 73,691 tons of tailing. Working expenses totaled $4.28 per ton. The profit was $778,000 and surplus $1,010,000.

WAIHI-PAEROA GOLD EXTRACTION CO., LTD.

As mentioned before in this journal, this Company has a dredging plant, 22 tube-mills, Pachuca tanks, and vacuum-filters, recovering and treating tailing from the Ohinemuri river, New Zealand, washed down from the mills at Waihi, Waitekauri, and Karangahake. During the half-year ended June 30, 1914, the dredge had to work on shallow bars, due to a dry summer; but a new Priestman dredge is to be installed. The plant treated 70,200 tons of tailing yielding gold worth $89,000, against 71,200 tons and $108,000 in the previous half-year. The profit was $4300. Since early in 1912 the output was 304,400 tons for a profit of $60,000.

ROOIBERG MINERALS DEVELOPMENT CO., LTD.

This Company operates a tin mine in the Transvaal, and the report of E. J. Way covers the year ended June 30, 1914. Ore reserves are estimated as 20,097 tons, averaging 4.95% metallic tin. The 10-stamp mill crushed 29,181 tons, producing 1294 tons of concentrate assaying 68.51% metal. The recovery was 78.81%. An average of £174 per ton was received for the tin, against £218 in 1912-13. The revenue amounted to £152,889; profit, £55,805; amount from last year and interest, £73,888; dividends, £31,500; and carried forward, £22,787. Costs were reduced by $1.46 per ton of ore milled. While development at depth has not been up to expectations, the property is in a sound condition.

CAMP BIRD, LIMITED

The report of this well known Company covers the year ended June 30, 1914. In the directors' report, details are given of the Company's trouble with the failure of the Canadian Agency, Ltd., Chaplin, Milne, Grenfell & Co., and A. M. Grenfell, which was published in this journal of July 25. A technical committee was appointed, and with the change of offices in London there has been a saving of about £2000 per annum. The Company owns 1,122,901 shares of the total of £1,500,000 of Santa Gertrudis, Ltd., but on account of the revolution in Mexico no dividend was paid for the year. The Messina (Transvaal) Development Co., Ltd., was also mixed up with the Grenfell failure, and the Camp Bird company holds a considerable interest in it. On June 2, according to R. J. Frecheville, the Messina mine contained ore reserves, to No. 9 level, amounting to 247,000 tons of 9% copper. Further development has been good. The mine, mill, and smelter are in first-class condition. In the Central American Goldfields Syndicate, Ltd., the Camp Bird has invested £47,200 of the capital of 5000 £1 shares and £100,000 7% notes. Litigation will probably arise over the title to the properties acquired in Nicaragua, and operations are suspended for the present. Owing to the war, it is impossible to forecast what will be the ultimate liquidation of certain loans, etc., and the directors have written off considerable amounts in respect of losses. In the assets are shares in several companies valued at £905,184 net; cash, £30,916; stocks, £16,999; and sundry debtors, £55,371. Among the liabilities are sundry creditors, £18,159; outstanding dividends and debenture interest, £14,360; and balance forward to the current year, £5392.

The general manager, William J. Cox, reported as follows concerning work at the mine and mill: The general situation is no better than as advised in the report for 1913, but rather exaggerated with increasing depth and narrowing stoping widths in hard ground. Development totaled 3605 ft. Work is confined to the territory reached through No. 3 shaft, and a vein of increasing width, with depth, throughout a length of about 500 ft., lessened at each end to a width comparing with that in the upper levels, thus forming a lenticular 'bulge.' At between No. 4 and 5 levels it was 12 ft. wide, increasing to 30 ft. 400 ft. deeper, and for a short length on No. 8 it is 60 ft. wide. This forms the productive area of the mine. Quartz predominates in the vein filling, and only a small percentage is profitable. The profitable ore has hematite for its base, and is freakish, as it contains iron, zinc, and lead sulphides. It occurs in streaks, lengths being less persistent and narrower with depth, and less regular in its relation to the walls. The extreme west end of the mine is leased to the Argo Mining Co., and 1145 ft. of work failed to reveal profitable ore. Ore reserves are estimated at approximately 25,709 tons, which will yield a profit of $307,648. On June 30, 1914, there was 17,616 tons of ore broken in stopes.

The stamp-mill crushed 30,595 tons of ore yielding metals worth $801,079, against $675,630 last year. Details of mill work will be given in another issue of this journal. The year's profit was $337,000, of which $218,000 was paid to preference shareholders.

SANTA GERTRUDIS COMPANY, LTD.

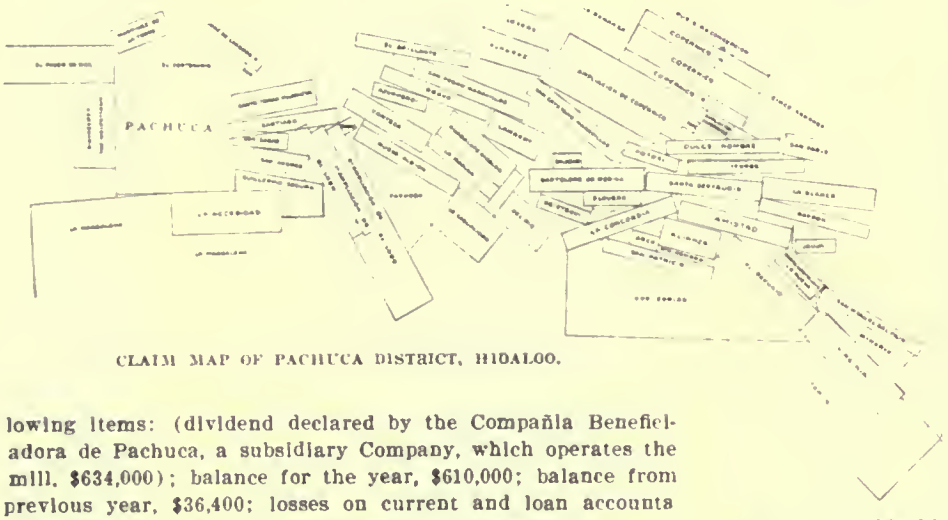
In many respects, the report of the directors of this Company for the year ended June 30, 1914, is similar to that of the Camp Bird, an abstract of which appears on this page. The report of the general manager, Hugh Rose, contains the following information:

No prospecting was undertaken. Development was continued vigorously, and amounted to 19,119 ft., of which 4853 ft. was charged to mining. The cost of development and mining was 56c. and $2.32 per ton, respectively. Deferred development written off was 8c., making a total underground cost of $2.96, against $4.28 for the preceding year. No. 20 level has been driven for 1400 ft. west of the east boundary. The vein is as strong as ever, with no material change in the andesite walls. Profitable ore exposed is limited to two shoots, 270 and 350 ft. long, respectively, with a stoping width of 5 ft. worth $5.52. Further work at depth is to be done through the interior shaft, now sunk 221 ft. below No. 20 level. It will be continued to 400 ft. Three large orebodies were found lying in the hanging wall of and near the North vein. So far as opened, one shoot, from No. 16 to 100 ft. below No. 19 level, is 370 ft. long, 110 ft. wide, and 470 ft. deep, estimated to contain 544,000 tons. Of this, 272,000 tons will average $7.04 per ton, the remainder unprofitable. The second shoot, on No. 17 level, is 230 ft. long and 20 ft. wide, and assays $12 per ton. And the third shoot, on No. 9, 11, 13, and 14 levels, is wedge shaped, 24 by 84 ft., worth $8.96 per ton. These discoveries show the importance of cross-cutting the hanging-wall area. Work in the Necesidad mine gave encouraging results. Ore reserves are estimated by the advisory engineer, William J. Cox, as 1,194,000 tons, which should yield a profit of $4,128,000, that is with silver at 59⅜c. per ounce, as in the last report [Silver is now 48½c.—EDITOR.]. Water pumped from the mine varied from 800 to 1200 gal. per minute, an increase over previous years.

Owing to the Mexican revolution, and occupation of Vera Cruz by United States troops on April 21, 1914, regular production was suspended, but by July 6 conditions allowed of a resumption to about 66% capacity. During the year the new mill treated 307,079 tons of ore, the March output being 32,849 tons with 60 stamps. Bullion recovered amounted

to 16,587 oz. gold and 3,182,341 oz. silver, worth $2,223,000. The recovery was 92.78%. From the Guadalupe mill was recovered 233 flasks of quicksilver from the old *patio*, also other residue, which yielded a net return of $2210.

The accounts are not clear as to profits, but show the following items: (dividend declared by the Compañia Beneficiadora de Pachuca, a subsidiary Company, which operates the mill, $634,000); balance for the year, $610,000; balance from previous year, $36,400; losses on current and loan accounts (Grenfell affair), $110,500; depreciation of investment, $45,200; cash, $452,000; and balance to current year, $456,000.



CLAIM MAP OF PACHUCA DISTRICT, HIDALGO.

GRANBY CONSOLIDATED MINING SMELTING & POWER COMPANY, LTD.

A short abstract of the financial results of this Company for the year ended June 30, 1914, appeared in the *Press* of October 17. Further details of operations are as follows, as given by the general manager, F. M. Sylvester; superintendent of mines, O. B. Smith; superintendent of smelters, W. A. Williams; and mine superintendents at Phoenix, Valdez, Ketchikan, and Anyox, C. M. Campbell, H. J. C. MacDonald, E. E. Campbell, and N. W. Sweetser, respectively.

Ore reserves in the various mines are as follows:

	Tons.	Tonnage available per day.
Phoenix	4,691,531	3,000 to 4,000
Anyox	18,153,000	2,000
Mamie	135,200	300
Midas	116,344	100
It-Dean	5,000	30
Total	23,101,075	5,430

The Phoenix ore yields 17 lb. copper, 0.033 oz. gold, and 0.2 oz. silver per ton; Anyox, 1.4 to 2.2% copper, and 30c. per ton gold and silver; Midas, 4% copper, 0.065 oz. gold, 0.46 oz. silver; Mamie, 2.25% copper and 25 to 50c. per ton in gold and silver; and It-Dean, $15 to $20 per ton. Development at Phoenix amounted to 13,647 ft. underground, and 19,670 ft. of diamond-drilling, a total of 121,495 ft. and 75,812 ft., respectively. All mining costs totaled 80c. per ton. At Anyox, work covered 5319 ft., of which nearly half was on the 530-ft. level. Thirty holes were drilled, a total of 6072 ft. from the surface and various levels. In all, there have been drilled 166 holes, equal to 43,591 ft. The high-grade ore, 9,563,000 tons of 2.2% copper and 30c. gold and silver, is surrounded by 8,589,500 tons of low-grade material, with 0.6% copper, making a total of 18,153,000 tons averaging 1.4%. Mining costs should not be over $1 per ton. At the Midas mine, near Valdez, Alaska, 2000 ft. of work was done, 1500 ft. being in ore as described above. This ore should be extracted and delivered to the boat at about $2 per ton. A wharf, ore bunker belt, 5½-mile tramway, 200-hp. Diesel engine power-plant, 30-hp. Foos engine, 15-hp. Fairbanks-Morse distillate engine, and other equipment was erected. The Mamie property is near Hadley, on Prince of Wales island. There are eight claims, on which the Granby company started work in December 1913. Work done in charge of Mr. Heidman, the foreman, has shown that the zone rather than being a number of small orebodies, as described in a report by the U. S. Geological Survey, is largely one large lense with 'islands' of barren silicious rock occurring throughout the lense. Two other smaller shoots so far have no connection with the large body. Extensive faulting has caused this formation. The future of the mine is promising. The It and Dean mines are on the same island, four miles from Kasaan. Work was started by the Company in June 1914. The ore consists of chalcopyrite in a gangue of garnet, epidote, and calcite. It averages 40c. per ton gold to each 1% copper. There are five lenses of ore opened. Natural advantages for operation are numerous.

The Grand Forks smelter had a high average of furnaces in blast, with good tonnages smelted, and good recovery. Silica was high in the slag. Costs were a trifle higher. There were 208 men employed in charge of W. B. Bishop and heads of departments. At Anyox the first furnace was blown in during March. There were some mechanical troubles, especially with the worm-drive of the converters. Metallurgical problems presented include the trouble with fine ore. Mr. Bone and others did good work in this new plant. During the year the smelters did the following work:

Mine.	Tons smelted.	Metals produced.	Value.
Phoenix	1,201,955	23,320,097 lb. copper	.....
Anyox	63,105	435,275 oz. silver	.....
Other	23,940	43,882 oz. gold	.....
Total	1,289,000	.....	$4,504,766

The total expenditure was $3,882,695, or $2.73 per ton of ore, and 11.5c. per pound of copper. The profit was $622,071; surplus from 1912, $3,199,271; dividends, $899,900; interest, etc., $182,520; surplus remaining, $2,738,922. There was a sum of $3,002,691 spent in developing and equipping the Anyox mine.

BROKEN HILL PROPRIETARY COMPANY, LTD.

The fifty-eighth half-yearly report of this 'Barrier' company, New South Wales, covers operations for the period ended May 31, 1914. The manager, G. D. Delprat, reported as follows:

Two diamond-drills were engaged in prospecting ground outside of the known orebody by means of horizontal holes from the 400, 500, 650, 800, and 1000-ft. levels, but nothing was found. Working two shifts produced 147,577 tons of ore.

The mills treated 139,991 tons of sulphide ore, yielding 24,059 tons of concentrate assaying 61.46% lead and 27.02 oz. silver per ton. The Luhrig vanners have been scrapped, and six additional Wilfley tables installed. With the concentrate from the regrinding plant the total output of lead concentrate was 27,395 tons. The flotation plant treated 168,558 tons, producing 37,745 tons of zinc concentrate assaying 46.33% zinc, 6.65% lead, and 12.89 oz. silver per ton.

The Port Pirie smelter, with four furnaces, treated 109,752 tons of mixed material, producing 48,404 tons of lead-silver bullion. The Dwight-Lloyd plant treated 44,445 tons of concentrate prior to smelting. The refinery produced 2,067,182 oz. silver, 916 oz. gold, 40,125 tons lead, and 221 tons of antimonial lead. The distillation plant yielded 2043 tons of spelter and 248 tons of blue powder.

Revenue for the period was £1,147,196, and gross profit £180,251. Dividends totaling £107,050 were paid.

MINING DECISIONS

Mining Claims on Alaska Seashore

The provisions in the Acts of May 14, 1898, and March 3, 1903, extending the homestead laws to the territory of Alaska, providing that no entry shall be allowed extending more than 160 rods along the shore of any navigable water, and that along such shore a space of at least 80 rods shall be reserved from entry between claims, have no application to mining claims asserted under the general mining laws as extended to Alaska.

Francis Clarno (Land Department), 43 Land Decisions, 120. February 19, 1914.

Subsurface Support—Right to Waived

A deed to the surface of coal land excepted, "all coal and minerals beneath the surface * * * with the right to mine and remove the same * * * without thereby incurring in any event whatever any liability for injury caused or damage done to the surface of said lot or buildings, which are now or hereafter may be put thereon." Held that the grantee or his successors in interest under said deed could not recover for damages to the surface resulting from insufficient support given the same by parties mining beneath the same.

Graff Furnace Co. *v.* Scranton Coal Co. (Pennsylvania), 91 Atlantic, 508. March 30, 1914.

Miners' Liens—Effect of Assignment

Under the Oregon code, an assignment of a miner's lien, prior to its recordation, would be invalid, carrying title only to the debt and not to the right to perfect the lien. The affidavit of verification may be made by a person other than the lien claimant providing he has knowledge of the truth of the facts set forth in the affidavit. A sale of mining property on foreclosure of a mortgage extinguishes the liens of a mortgage, so that they do not affect a subsequent proceeding for a lien against the property for labor and supplies. Failure to post notices of non-responsibility by a lessor renders the mine subject to liens for obligations incurred by the lessee.

Loud *v.* Gold Ray Realty Co. (Oregon), 142 Pacific, 785. July 14, 1914.

Placer Patents—'Known Lodes'—When Excepted

Six lode locations were made in October 1912, upon land for which placer patent was applied in 1873. The land was a typical gulch placer gold claim. Some lode outcroppings had attracted attention in early days and lode locations were made as early as 1865, abandoned, relocated, and again abandoned. The lodes claimed by defendants to be 'known lodes' excepted from operation of the placer patent, were shown to have been discovered in the bedrock after removal of the overlying placer deposits. Held, that no valid location could be based on such a discovery. The court said: "Float, outcroppings, lodes, and abandoned locations separately or combined, are not sufficient to constitute a 'known lode' within the exclusion of the placer law. To be impressed with such character, the lode must, at the time of the application for the placer patent, be clearly ascertained and defined, and of such extent and content that it will then, in view of conditions then, justify development and exploitation and because of which the placer claim is valuable and more valuable for placer mining purposes." Mere lapse of time, however, does not estop a lode claimant from making a valid location of a lode claim as against a placer patentee. The exception of 'known lodes' applies for all time as to the United States or any one claiming under the United States.

Barnard Realty Co. *v.* Nolan (Montana), 215 Federal, 996. July 25, 1914.

BOOK REVIEWS

Laboratory Course in Electrochemistry. By Oliver P. Watts. P. 150. Ill., index. McGraw-Hill Book Co., New York, 1914. For sale by the *Mining and Scientific Press*. Price, $1.

Electrochemistry is an important branch of chemical work, and is making great strides, especially in separation of metals. This little work was written primarily for the author's classes in the University of Wisconsin, and embodies notes originally prepared by C. F. Burgess, former head of the chemical engineering department of that institution.

Corporation Laws, Arizona, California, and Nevada. Compiled by Calvert Wilson. P. 288. Index. Baumgardt Publishing Co., Los Angeles, California. For sale by the *Mining and Scientific Press*. Price, $2.

The corporation laws of states and countries are often puzzling and of great length. In this volume are given a general outline of these laws in the above states of the Union, pertaining to general private corporations. It also contains the forms in ordinary use for corporation purposes, not including forms for creating bond issues, and the like. It is brief but practical.

College Physiography. By R. S. Tarr and Lawrence J. Martin. P. 837. Ill. The MacMillan Company, New York, 1914. For sale by the *Mining and Scientific Press*. Price, $3.50.

The text-books of physiography written by the late Professor Tarr are deservedly widely known. At the time of his death he had in preparation the manuscript of a larger and more comprehensive work on the subject. This came into the capable hands of L. J. Martin, one of his former students, now at the University of Wisconsin, for completion, and it is no disparagement to Tarr to say that the completed work seems to be the gainer thereby, since two heads are proverbially better than one. All of the last seven chapters, the bibliographies, and much of the remainder of the text are due to Mr. Martin. The book is primarily intended as a text for college students, but it is compendious enough to serve as a reference book, and readable enough to appeal to the general reader interested in the scientific description of the visible features of the world he lives in. For the general reader the book would have been improved if the discussion of each physiographic feature had been sufficiently extended to show its economic significance. In Chisholm's Commercial Geography, for example, the economic significance of physiographic features is discussed by countries, but it would be somewhat more logical, and more illuminating, to treat them according to topics. Thus the disturbing effect of the advance and retreat of glaciers on road-building and railroad building in the vicinity, the work of the winds as affecting agriculture and commerce, the course and rate of flow of rivers as affecting trade, the effect of ocean currents and oceanic winds on international trade, and similar topics might all be discussed in connection with the description of the phenomena concerned, with the result that the college student would be able to perceive the economic significance of any given set of conditions encountered in his travels. To some extent this has been done in the present volume, as in the discussion of the Allegheny plateau, on page 513, but it might well have been pushed even further. The illustrations in the book are unusually good, having been culled from a great range of sources. The use of comparatively fine print is a slight drawback which was probably caused by a commendable desire to keep the weight of the book down to a point where it would not be a burden to the reader. The study of physiography is a topic which deserves more attention by the general public, and it is to be hoped that this readable book will conduce to that end.

THE ITABIRITE IRON ORES OF BRAZIL. By E. C. Harder. Reprint from *Economic Geology*, March 1914. P. 11. Ill. Also THE IRON INDUSTRY OF BRAZIL, reprint from *Transactions* of the American Institute of Mining Engineers.

REPORT OF THE ILLINOIS STATE MUSEUM OF NATURAL HISTORY. By A. R. Crook. P. 73. Ill. Springfield, 1913. A brief account of the work and collections of this, a "state institution for the people, for education, for science, and for business."

INLAND LAKES OF WISCONSIN; THE HYDROGRAPHY AND MORPHOMETRY OF THE LAKES. By Chancey Juday. Wisconsin Geol. & Nat. Hist. Surv., *Bull.* 27. P. 137. Ill., index. Madison, 1914.

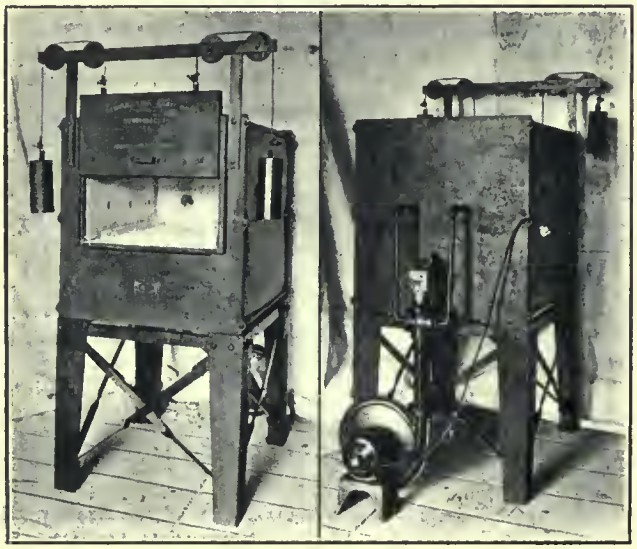
MISSISSIPPIAN BRACHIOPODA OF THE MISSISSIPPI VALLEY BASIN. By Stuart Weller. State Geol. Surv. Illinois, Monograph 1. Text and plates. 2 vol. P. 508. Ill., index. Urbana, 1914. This is an elaborate and authoritative scientific study of the sort that underlies and makes possible the highly useful work of the modern economic geologist. It is a work for specialists, though in the introductory pages is given a general statement regarding the classification of the Mississippian rocks (the series in which the Joplin zinc ores occur) which makes available to the general worker the most recent results of the specialist.

New Machines and Devices

A Laboratory Roaster

In the determination of the proper metallurgical practice for the treatment of ores it is essential that a thorough investigation be made of all possible treatments and that one chosen which proves to be the most economic. Testing laboratories for making such thorough investigations are few, as such tests require such a wide variety of machinery and equipment. However, in the more modern laboratories and ore testing plants are to be found equipment for conducting such tests.

The general construction of this roaster will be seen from the accompanying halftone, showing two views of it. The hearth of the furnace is 20 by 30 in., thereby affording ample space for a fair sample of the ore to be tested. In each sidewall of the furnace are three pyrometer holes, seen in the



ROASTER SHOWING FUEL OIL BURNER.

halftone. These holes are positioned at such an angle that it is possible to place the pyrometer in such positions in the ore-bed that one can take accurate readings and keep a complete record of the performance of the furnace. The fuel is admitted through the rear of the furnace by means of a Case low-pressure fuel-oil burning system, shown in the left of the halftone. The oil flows by gravity to the oil burner and the air is supplied by a direct-driven motor blower of special design. The blower is driven by a ½-hp. motor and supplies 4000 cu. ft. of air per minute. Electricity for the blower may be supplied by connecting with the ordinary lamp socket.

In the rear of the furnace will be seen two air vents connected with the blower. These have been provided in order that after the roast has been completed and sulphur driven off, the air may be turned into the furnace over the charge at the rate of 4000 cu. ft. per minute and the oxidation thus made complete.

The furnace is strongly built and the lining is easily replaced in a few minutes. In addition to its use as a laboratory roaster, it will also undoubtedly find a field in metallurgical plants as a convenient means for roasting precipitates. This interesting little roaster is manufactured by the Denver Fire Clay Co., Denver, Colorado, and the roaster shown is the first to be built and will be installed in the laboratory of the mining department of the University of Wisconsin.

Commercial Paragraphs

HYATT ROLLER BEARING CO., Chicago, is distributing a folder addressed to the buyers and builders of machine tools.

SUTTON, STEELE & STEELE, Denver, Colorado, is operating a demonstrating and custom mill, which treats a wide variety of ore by dry concentration methods. The mill equipment includes crusher, dryer, elevator, de-duster, storage bins, mechanical sizer, dry concentration tables, dry jigs, rolls, and other equipment, including static electric machines.

PAWLING & HARNISCHFEGER CO., Milwaukee, Wisconsin, has issued Bulletin 301-A, entitled 'The Application of the Electric Hoist.' Whenever loads are too heavy to be moved by one man, the electric hoist is recommended. The hoist discussed is an overhead monorail hoist, traveling on the lower flanges of an I-beam. The illustrations show the application of this type of hoist to a large variety of purposes.

WESTINGHOUSE ELECTRIC & MFG. CO., of Pittsburgh, Pennsylvania, has just issued a pamphlet entitled 'Central Station Power in Coal Mines.' The pamphlet is devoted to the use of electricity in coal mines and points out the advantages of obtaining a power supply from central station plants. A number of tables are given showing the cost of operation; curves are also given showing the day and night lode in the mines.

LEHIGH CAR WHEEL AND AXLE WORKS, Catasauqua, Pennsylvania, has recently issued Catalogue 50, entitled 'Fuller Quality Products,' which contains the new list prices covering the face-hardened sprocket and traction wheels, also general descriptions of the high-grade chilled charcoal iron castings for all uses manufactured by this Company. The catalogue is illustrated and contains a great deal of information concerning the Company's products.

'The THEAMIT PROCESS OF PIPE WELDING' is the title of a new publication by the Goldschmidt Thermit Co., New York. The object of the booklet is to call attention to the many advantages of the thermit process for pipe welding in plants for high-pressure steam, hydraulic, and compressed-air pipelines. The process is described in detail, telling how the welds are made and giving full information on the cost of this operation. The booklet is fully illustrated and contains a great deal of information on this type of welding apparatus. Another attractive publication by the same Company is entitled 'Thermit Insert Fully Welded Rail Joint.'

ALLIS-CHALMERS MANUFACTURING CO., Milwaukee, tienes por distribucion Boletin No. 1808. Este catalogo es discriptiva de maquinaria de extraccion, dando mucho espacio a malacates. Esta Compania habienda tenida mucha experienca en el diseño y funcionamiento de toda clase de maquinaria de extraccion, disfruta de opportunidades excepcionales para alcanzar un conocimiento perfecto de todas las exigencias y la solucion de los problemas de ingenieria relacionados con la maquinaria de extraccion. La Compania fabrica malacates de todas clases por todos usos. En este catalogo son presentanda con illustraciones y detailles una discusion de esta clase de maquinaria.

THE Rand gold output is increasing; it was 733,746 fine ounces in October as compared with 702,170 in September, and 718,431 in October 1913.

COMPLAINT has been made that men answering advertisements for situations open, at times receive no acknowledgment of the application, to their own inconvenience and occasional loss. The courtesy of a reply should certainly be extended to one who, in a sense, has answered your request for information. This is all the more imperative since the advertisements are usually 'blind' and the applicant has not even the means of knowing whether the work lies in a region to which he would willingly go. Any company desiring to maintain its anonymity can send replies through the publisher of the advertisement.

ORGANIZATION of the California Metal Producers' Association has been completed by election as directors of Messrs. Albert Burch, George W. Starr, E. C. Hutchinson, C. E. Knox, Newton Cleaveland, George W. Metcalfe, and Seeley W. Mudd. The finance committee consists of Messrs. J. H. Grady, Henry Malloch, and William Hague. Mr. Burch was made president, and Messrs. Metcalfe and Hutchinson vice-presidents. Mr. John Mocine, recently in the service of the Goldfield Consolidated Mines Company, has been selected as secretary-treasurer, and an active canvass is being made to complete the membership.

CONFESSION of Boris Thomason clears the mystery regarding recent fires at Goldfield and Tonopah, and fixes the responsibility upon the I. W. W. of which Thomason has been a leader in the mining districts and at Stockton, California. Thomason has been sent to the penitentiary for twenty years, but the I. W. W. as a trouble-making organization is still at large. We have every sympathy for the men now out of work, many of whom are recruited to the ranks of the I. W. W., but the first function of a civilized government is to maintain order, and we do not believe that the way to better things is through such means as the I. W. W. has adopted. Also, we believe that quick determined work by the officers of the law will forestall much of such trouble. We would not like to look forward to living under martial law, but we would rather live under it than no law.

SAN FRANCISCO members of the Mining and Metallurgical Society of America signalized the beginning of the winter season by a 'home coming' dinner to Mr. F. W. Bradley, at the Palace Hotel last Monday. The occasion was particularly enjoyable and the members and guests were glad to hear informally of the progress of work at Juneau, Treadwell, and Kellogg, where Mr. Bradley had been spending a long summer of hard work. It is pleasant to record that developments both in Alaska, where the first unit of the Alaska Juneau mill was under study, and in Idaho, where dry chlorination is being tried on lead ores, have been most satisfactory. Mr. C. H. Munro discussed briefly the black sands of the California beaches. Mr. Seeley W. Mudd gave interesting details of the newly discovered platinum deposits of southern Nevada, and others contributed to a general discussion that was stimulating and helpful. Such dinners cement friendships and develop professional solidarity. They are all the more pleasant when made the means of expressing appreciation of the work and attainments of a distinguished member of the profession.

PLANS for 1915 at San Francisco have been but little changed by the war in Europe. The Panama-Pacific Exposition will open on time and the great buildings will be filled with exhibits from all parts of the world. The Engineering Congress will be held in September as originally planned. Of the 290 papers for the latter originally contemplated, 220 are either definitely promised or well assured, including papers from England, Spain, Sweden, Holland, Canada, India, Italy, China, Japan, Australia, and various South American countries. A few from the war zone are uncertain, though some of them are expected. It is believed, however, that by substituting other papers that have been offered, the general plans outlined last year may be realized. The honorary president of the Congress will be Colonel G. W. Goethals. The honorary vice-presidents include Messrs. Richard Beck, Sir J. H. Biles, Otto T. Blathy, Commander Christian Blom, André Blondel, C. E. L. Brown, Emil A. Budde, Henry Le Chatelier, Hermann Hullmann, William Henry Hunter, Luigi Luiggi, Rear Admiral Yoshihiko Mizutani, W. M. Morday, Sir Charles Parsons, Jean L. de Pulligny, V. E. Timonoff, R. P. J. Tutein-Melthenius, H. H. Vaughn, and Sir William Willcocks. The coöperation of these men assures an interesting program.

COPPER QUOTATIONS

Discussing copper quotations last month, we incidentally mentioned *The American Metal Market*. That journal, greatly to our surprise, chose to interpret what we wrote as an attack, and replied with a couple of caustic criticisms without waiting for an exchange of letters which, we are glad to say, removed much of the misapprehension. Our excitable contemporary protests that it does not depend upon the New York Metal Exchange—a correction we gladly make, merely calling attention to the fact that we said "depend largely"—and advances argument to show that its quotations afford a better guide than do those of the "technical journals." As to that, more later. Let us first acknowledge an error into which we fell in stating that the quotations in *The Iron Age* agreed with those of the *Press* rather than of *The American Metal Market*. Since the first of the year, apparently, the reverse has been true. Our statements were based upon a fairly complete investigation made some two years ago when we were studying the whole situation. The figures should have been checked by recent quotations.

The American Metal Market characterizes as "stupid" and "irresponsible" our suggestion that if quotations had not been withdrawn copper would have dropped to five cents or less. We see no reason to change our opinion, and that certainly was the belief of several of the largest producers early in August. It is proverbial that 'hindsight' is easier than foresight, and foreign demand has been better than was anticipated. Certainly no one doubts that if quotations had been continued the price would have fallen far below the cost of production, which is the main point. The particular number of cents suggested is unimportant. The effect would have been the closing of plants, and as the relations of supply and demand became gradually adjusted the price would have risen to cover cost, at least, of the companies continuing to produce. The same result has been brought about in another way, with the difference that there has been no sacrifice of stocks of copper at absurdly low prices. Withdrawing quotations was a war measure designed to stop the flow of contract copper, as we stated. It was a distinct benefit to everyone concerned, save metal users, who would, naturally, have liked to profit from panic prices. Quotations have now been resumed, and in the interim we have printed the prices at which copper has been paid for, but we have no illusions as to there having been an open market for copper for the past two months, whatever professional traders in New York may hypnotize themselves into believing.

The reason that average quotations do not check with average returns for the year in the case of the larger companies has already been sufficiently explained. There is a radical difference between selling a raw product such as ore, where steady shipments are the first consideration, and marketing a finished metal already in the warehouse and ready to be moved when the market is favorable. The quotations we give are those at which copper in ore is paid for, which is the price that mainly concerns our circle of readers who are ore producers. We believe that the prices are at the same time those at which the metal companies sell copper. It is to be remembered that our quotations, being for record rather than for trading, represent transactions already closed. At best they are two days old when made public. Under these conditions it is possible to get information that no metal company could afford to give to a reporter if it was to enter into prices used for trading the next day. Differences of opinion as to the market on any particular day exist or there would be no trading, but at the end of the week it is possible to know the price at which metals did move on each day, and that is the fair and right price for settlement of deals as of that day. We reiterate our protest against the implication that differences in opinion are necessarily founded in differences in honesty.

AMERICAN MINING CONGRESS

Phoenix, Arizona, has just been visited by a serious fire which destroyed a number of its main business buildings. Phoenix, however, can be expected to prove true to its name, and in the meantime facilities for entertaining the visiting mining men and their wives during the meeting of the American Mining Congress, December 7 to 11 inclusive, are ample and uninjured. Under the capable chairmanship of Mr. Will L. Clarke, an attractive series of local excursions and receptions has been arranged and the delegates and guests will be certain to see Arizona at its best. The program committee has been not less active. The subjects announced for discussion include the topics of Western mining conditions, mining investments, safety, federal aid to mining and mining schools, water-power development, conservation, workmen's compensation, developments on reservations, rights-of-way on the public domain, mine taxation, revision of mining laws, and compulsory arbitration; certainly a comprehensive list. Many of these topics are controversial, and all of them concern matters that mining men should discuss frankly among themselves. Possibly it would have been better to abbreviate the program and centre it upon a few definite subjects, since one or two measurably well rounded out conferences accomplish more than much desultory speaking. We understand that the conference idea is to dominate the meeting in place of the older one of a series of set speeches. We are glad to see this, as also the persistent study by the Congress of the business side of mining. It is in this, as we believe, that its largest field of usefulness exists, since its membership includes non-technical as well as technical men.

One topic, not down upon the program, is sure to come up for thoughtful discussion, and that is, the future of the Congress itself. As is well known, the organization has never been adequately financed for the work it has undertaken. A report made public this year by the Ways and Means Committee showed that

membership fees have not yielded enough to meet expenses and that in fact the work of the past few years has been accomplished largely through the self-sacrifice of the secretary, Mr. J. F. Callbreath, Jr., to whom the Congress has been chronically in debt. The matter is given especialy significance at this time through the circumstance that Mr. Callbreath has had, this year, to abandon active work for a time and retire to a sanitarium. We are glad to report that his health and strength are returning, but a great public work such as the Congress has accomplished and such as it has yet to do, ought not rest so largely on the shoulders of one man. The situation is a grave one and should be frankly faced. Important as the work is, it should be abandoned for the time unless adequate support can be assured. We hope no such retreat may be necessary, and we trust that at the Phoenix meeting the members will not only have the enjoyable visit that is assured, but will also find a way to meet the very pressing needs of the Congress itself.

SEEKING SOUTH AMERICAN TRADE—A WORD OF CAUTION TO HOME FOLKS

Elsewhere in this issue we present a review of South and Central American countries from the business standpoint. Much of what has been said in the public prints recently concerning the possibility of developing increased trade with South America has been so visionary and ill advised that it will be well briefly to review the actual situation. In the first place, it is evident that no one wants to sell goods to South America unless some provision is made for paying for them promptly. It is equally evident that South American countries can only pay for the goods which they import by selling their own products, either in this country or in Europe. Any country is likely to buy most of its goods in the same market in which it sells its products, just as the farmer who brings a basket of eggs to town buys his supplies in the store in which he sells his eggs, and for the same reason: any buyer will make better terms with a seller who is willing to take out his credits in trade. A fundamental difficulty is here involved, for the main products of South American countries are those which this country also exports largely. Coffee, rubber, wool, hides, beef, tin, and nitre are all South American products which we must have, however, and with proper cultivation of markets practically every South American country can sell enough of its products here to establish sufficient credit to secure large quantities of American-made goods. Another difficulty has been the absence of adequate banking facilities. Until recently the law forbade our national banks to have foreign branches. This blunder has now been corrected and the National City Bank of New York has already established branches in Rio de Janeiro and Buenos Aires, and doubtless others will soon follow. A difficulty remaining to be overcome is that there is no direct exchange of our money for South American money. A purchaser in Brazil, for example, is obliged to buy, in Brazilian money, exchange on London in pounds sterling and then negotiate this in New York to pay his bill there in dollars. Even the freight between South American ports and this country is reckoned in pounds sterling. This extra exchange involves extra cost, which is to our disadvantage. It is hoped that when American banks are firmly established in South America this can be overcome, and a daily exchange rate established between the United States gold and the moneys of the different South American countries.

Another problem that will be difficult for us to meet is the lending of money to these countries. Practically every one of these countries is a borrower of capital, some borrowing in very large amounts. Every borrower is under a good deal of pressure to do business only with the interests which lent him the capital for financing his operations. Mr. C. M. Pepper, former South American agent of the Department of Commerce, has estimated that the United States must be prepared to lend South American countries $500,000,000 in the next five years if we expect to 'capture' South American trade. It is dangerous to prophesy what will happen after this war, but it seems beyond the bounds of possibility that we shall be able to furnish anything like such a sum. Doubtless a good deal more trade than we now have can be secured without making such huge loans, but it is well to keep in mind that the whole South American trade is not to be ours for the mere asking.

We are keenly conscious in this country that the war in Europe has seriously and unfavorably affected us, and are perhaps inclined to overlook the fact that South American countries have been similarly affected. Brazil was in a precarious financial condition before the war broke out and had arranged to overcome her difficulties through large foreign loans which cannot now be placed. The European market for rubber and coffee is in large part cut off and, with the present low prices for coffee and rubber, increasing our trade with Brazil will not be as simple as rolling down hill. Argentina was also in a financial crisis before the war, and as nearly all her grain and much of her wool is sold in Europe, her situation is also serious. The largest sales made by Chile are of nitrate and copper to Europe, and both these products can now only be marketed in limited amounts and with difficulty. The copper and cotton exports of Peru are similarly affected, while the cocoa exports of Ecuador are finding a lessened market at a lower price. In short, if times are hard here they are likely to be harder in South America, and the expectations of immediate trade profits with South America must not be too rosy. On the other hand, having suffered in this way from the troubles in Europe, South American countries are the more likely to turn to us for mutual help, and if the two Americas stand together now, closer relations will be engendered that will bring big returns in the future.

A final word must be said as to methods of getting trade. It is absurd to send to Brazil or Peru a traveling salesman who has made a good record in the middle

western states and expect him immediately to send back large and profitable orders. A salesman must know the language and customs of the country, and must conform to those customs. The typieal drummer who is so obvious in railway cars and hotels will not get results in South America, where business is conducted at a slow pace with rather formal courtesy and along lines which seem to us stilted and old fashioned. Traveling expenses of representatives are high, from $10 to $20 per day, and often long distances must be traveled between points at whieh sales can be made. The handling of foreign orders by firms here is often highly unsatisfactory to customers. Orders are filled by clerks and office boys who know nothing of even the geography of the country from which the orders come, and the goods are often packed, consigned, and routed in a way which is greatly to the disadvantage of the customer, sometimes even in disregard of explieit instructions as to the method to follow. Within the past few years the Department of Commerce has been carrying on a campaign of education in this country which will doubtless be productive of excellent results. Trade with South America much resembles the situation of the Irishman who remarked that he could get on his new boots after he had worn them a few days. With increasing community of interest our trade relations with South America will grow, and there can be no doubt as to the large possibilities of the future.

ATTEMPTS AT DOMESTIC TIN PRODUCTION

Much attention has been directed of late to the apparently anomalous fact that although the United States consumes about 50,000 tons of the 120,000 tons of tin produced in the world, all of it is imported into this country, no foreign ore being smelted here, nor is there any appreciable production of domestic ore, most of that produced being sent abroad for smelting. It is interesting in this connection to review the attempts which have been made to develop a domestic production of that useful and essential metal. There seems to be a general impression that there are no tin deposits of any value in this country, but as a matter of fact there are several of distinct promise. Circumstances have been unfavorable to their development, and perhaps the most vital circumstance has been that the opportunities for profitable investment of capital in mining in this country during the past fifty years have been so great that some of them have been perforce neglected, while our prospectors have been unfamiliar with tin ore.

Perhaps the most promising of our deposits are those which lie along the border line of North and South Carolina, extending from Cherokee county, in the latter state, over into Lincoln county, North Carolina. Thirty years or more ago these were brought to the attention of Phelps, Dodge & Company, which firm took an option on a large area in which cassiterite occurs as an original constituent of pegmatite dikes. A careful study of the deposits made by Mr. A. R. Ledoux indicated that if worked on a sufficiently large scale the ore could be mined at a profit and would yield about 15 pounds of tin per ton of ore. The price of tin fluctuates widely and there was room for doubt whether it might not decrease to below 20 cents, the price at that time, at which the indicated operating profit would disappear, so the option was surrendered. Since then the area has been divided into small holdings, some of which have been worked in a rather desultory manner, and the Cherokee Tin Mining Company, at Gaffney, in South Carolina, and the Piedmont Tin Mining Company, at Lincolnton, North Carolina, are still engaged in developing their holdings. If it were feasible to organize a great operating company, like the Utah Copper, it seems quite probable that a notable production might be developed in this area. The climate is favorable, labor and fuel cheap. Even if concentrates only were produced at first, they could be marketed abroad, temporarily, as freight rates to Norfolk are cheap, and cotton ships take heavy material for ballast at low rates.

About the same time Benjamin Silliman, when in the Shenandoah valley of Virginia, about twenty-five miles from the well known 'natural bridge,' was handed a piece of mineral which proved on later examination to be cassiterite. Exploration disclosed numerous veins, resembling in many ways the famous deposits of Cornwall. They yielded twenty pounds of tin per ton in mill tests, and it would have been easy to finance the development of the mine if a valid title to the property could have been secured. Unfortunately the lands in question had been handed down from one generation to another without the making or probating of any will. As soon as their probable value became known, a host of claimants sprang up and litigation over the title became so involved that no mining company could be persuaded to risk investing its capital.

About the same time occurred the advent of Mr. Samuel Untermyer into the world of mining finance, a group of British investors being persuaded by him to put great sums into the Harney Peak Tin Mining Company, a corporation previously formed to work a group of claims near Harney Peak in the southern Black Hills of South Dakota. The tin-bearing veins proved to be of very low grade, much of the black mineral whieh many regarded as cassiterite in the hand specimen proved to be tourmaline. It was not long before the venture disclosed itself as a fiasco. Allegations of bad faith were made, long litigation followed which was of little benefit to the unfortunate investors, and the notoriety which the venture attained has undoubtedly reacted to discourage the investing of capital in tin mines in this country. Not far from this property are the mines near Tinton, South Dakota. These are of much more promise, but the first attempt to work them ended in failure, not due to the character of the ore, and the mortgage on the property was foreclosed by the Bank of Montreal. Since that time the property has been considered by more than one group of investors, but so far not much progress has been

made toward the reopening of the mines.

Of recent years a small amount of tin concentrate has been produced in Alaska, chiefly by dredging in an area a short distance east of Cape Prince of Wales. These deposits have been described in considerable detail in earlier issues of the *Mining and Scientific Press,* but while they are of local importance they have as yet only produced a fraction of one per cent of our domestic tin requirements. Some years ago it was proposed to smelt tin concentrate from the Malay peninsula in this country, thus rendering consumers here more independent of the fluctuations in the European tin market, but although the smelting plant was built it was never operated, for the government of the Federated Malay States promptly levied an export tax on all tin concentrate consigned to ports outside the British Empire, the rate being so heavy that operations here could not be conducted at a profit.

Since the period which we have been discussing, the tin deposits of Bolivia have been developed to a point where they yield nearly a quarter of the world's production of the metal. The tin concentrate has heretofore been shipped to Europe for smelting, but with the outbreak of war this became nearly impossible, and many of the Bolivian producers became keenly interested in the possibility of shipping their ores to the United States for reduction. This presents obvious advantages, since the distance from the west coast of South America to the Atlantic seaboard through the Panama canal is much less than to Europe, and if the tin, which is the chief export of Bolivia, were sold directly to the United States the imports of Bolivia would presumably be bought here rather than in Europe. There are difficulties in the way, however. Many of the Bolivian producers have ties with Europe in the form of invested capital, and if a smelter were built here which depended on buying ores in Bolivia it might reasonably be expected that strong competition in ore buying would have to be met as soon as peace is restored in Europe. Nor does it seem practicable to secure control of any large group of the mines on terms that are likely to appeal to investors. The Bolivian government has taken up the matter with Ladenburg, Thalmann & Company of New York, and the proposal has been made that the Bolivian government issue bonds to cover the cost of building a smelter near New York, to be operated under the supervision of Mr. R. M. Atwater, Jr., of Ladenburg, Thalmann & Company, as agent, the profits from the smelting enterprise accruing to the Bolivian government. Presumably the Bolivian government is not yet ready for public ownership of utilities, for it has not yet accepted this proposal. A variety of suggestions has been made by other interested parties, but no agreement has yet been reached, and the matter is still in a fluid state. The interest in the matter, both in Bolivia and this country, is so keen that some workable arrangement is likely to be devised, and after a half century of abortive attempts it seems quite probable that at last domestic production of tin will become a reality.

ORIGIN OF SAND FILLING

Sand filling or hydraulic stowing of mine workings is attracting attention in many mining districts. We print this week a lengthy abstract from a most interesting discussion of the subject by Mr. B. C. Gullachsen, presented to the October meeting of the North of England Institute of Mining and Mechanical Engineers and to be published in full in the *Transactions* of the Institution of Mining Engineers. Mr. Gullachsen discusses briefly but clearly the methods that have been found applicable on the Rand. Mining the ore, extracting the gold, and returning the waste to fill the stope, without even temporarily stacking the residue on the surface, is a new development of 'continuous processes' that warrants study. There is little doubt that filling systems must be used in many mines and districts where they are yet unknown, and Mr. Gullachsen's description is therefore welcome and timely. In one particular we disagree with him, and that is in giving credit for the development of hydraulic stowing to the operators in Silesia and in passing over as of minor importance earlier work elsewhere. The whole subject has been discussed informingly and authoritatively in *Bulletin* 60 of the United States Bureau of Mines. From that, confirmed by private communication from Mr. R. V. Norris and Mr. William Griffith, it appears that the distinction of developing the system belongs to the engineers of the anthracite region in Pennsylvania. As early as 1884 hydraulic filling was used, by John Veith at the Buck Ridge colliery near Shamokin, and the subsequent year Mr. Pardee used it at Hazleton. Shortly after it was employed at the Kohinoor colliery of the Reading company near Shenandoah, and by 1886 it was in common use throughout the Lehigh region. In 1890 filling was introduced as a regular practice at the Black Diamond colliery at Plymouth. About that time the district was visited by several German engineers, who spent some time in studying the practice and gave full credit to the Americans for its novelty. Since then it has been more rapidly adopted abroad than in the United States because the higher price received for coal and cheaper labor permitted refinements that have been regretfully postponed by many a thoroughly well informed American engineer. On the Rand and at Cripple Creek in Colorado, sand from the mills is used. In Europe material is commonly taken from neighboring hillsides, or from valley lands as at Japanese mines in Manchuria. In the anthracite region the main source of supply has been the culm banks, and this has materially reduced the cost of the work. This claim that the process originated abroad is not new and has been repeatedly disproved. *The Colliery Engineer* published the facts January 1912 (page 321), February 1912 page 385), and especially in May 1914 (page 537). We regret that Mr. Gullachsen was evidently not familiar with the true history of the matter, though the real merit of his article lies in the other part of his paper, and it will be widely welcomed.

Trade Possibilities in Latin America

AN EDITORIAL REVIEW

For many years there has been much public comment on the fact that the trade of the United States with the countries of Latin America is a comparatively small part of either our or their total trade, although it might perhaps be expected that the countries of the Western hemisphere would have the greatest amount of trade with each other. The interruption of trade between Europe and Latin America by the deplorable war now raging in Europe has brought this heretofore desultory interest to a focus, and merchants, manufacturers, shipping companies, and bankers are all giving much consideration to the means of increasing the trade between the United States and the countries to the south of it. How large the possibilities are can be seen by a glance at the following table:

	Area, Sq. miles	Population	Imports	Exports	Rank of U. S. Imports	Rank of U. S. Exports
Brazil	3,291,416	20,515,935	$ 258,000,000	$ 325,000,000	3	1
Argentina	1,135,840	7,200,000	365,000,000	320,000,000	5	7
Bolivia	911,146	2,267,000	23,000,000	33,000,000	9	11
Mexico	767,060	15,663,207	96,000,000	147,500,000	1	1
Peru	713,674	4,500,000	23,000,000	32,000,000	2	2
Colombia	482,329	5,032,000	17,000,000	17,600,000	1	1
Venezuela	364,000	2,685,606	12,500,000	18,000,000	1	1
Chile	294,665	3,500,000	130,000,000	125,000,000	3	3
Paraguay	145,000	800,000	6,400,000	4,100,000	6	10
Ecuador	120,000	1,500,000	8,000,000	16,000,000	2	2
Uruguay	72,210	1,112,000	48,800,000	49,300,000	4	4
Nicaragua	49,500	600,000	2,500,000	3,900,000	1	1
Guatemala	47,810	1,992,000	5,514,000	17,497,000	1	2
Honduras	45,000	553,446	2,600,000	2,450,000	1	1
Cuba	44,000	2,277,492	118,000,000	128,000,000	1	1
Panama	31,580	419,029	10,000,000	1,800,000	1	1
Costa Rica	23,000	410,980	8,000,000	8,500,000	1	1
Santo Domingo	18,045	673,611	6,300,000	11,000,000	1	1
Haiti	10,204	2,000,000	7,948,000	18,554,000	1	1
Salvador	7,225	1,700,000	3,700,000	7,300,000	1	1
Totals		75,402,306	$1,152,262,000	$1,286,501,000		

How this trade was distributed is indicated by the next table, which shows the total imports of all these countries from the principal nations:

Great Britain	$322,036,347	Belgium	$48,747,164
United States	317,323,294	Austro-Hungary	9,026,478
Germany	216,010,418	Netherlands	8,293,859
France	103,220,223	Switzerland	6,189,050
Italy	55,494,412	All others	217,290,517

The relative distribution of the trade of the largest two countries is as follows:

ARGENTINA

	Imports from	Exports to	Total trade with
United Kingdom	$114,515,000	$117,125,000	$231,640,000
Germany	61,703,000	52,105,000	113,808,000
United States	57,057,000	31,257,000	88,314,000
France	36,301,000	34,790,000	71,091,000

BRAZIL

	Imports from	Exports to	Total trade with
United Kingdom	$ 77,519,000	$ 43,012,000	$120,531,000
Germany	52,952,000	51,864,000	104,816,000
United States	48,049,000	141,739,000	189,788,000
France	27,716,000	35,471,000	63,187,000

Thus, it is seen, although the United States holds first place in trade with the small countries of South and Central America, it has only third place with the countries which have the largest trade and is second as a whole.

There are a number of reasons why the United States does not have a larger share of the trade of South America. The first is that all the countries of this hemisphere are economically similar, having been comparatively recently settled, and all having progressed varying distances along the road from the production of raw materials alone, so characteristic of new countries, to the production of finished products which marks a later development stage. The natural trade relations of all American countries are with Europe, not with each other, just as farmers do most of their trading with city dwellers, and not with each other. The United States is now in process of transition from a producer of raw materials to a producer of finished products, and now is the time to get South American countries in the habit of buying their finished products from us. Another reason why European countries do so much business with South American countries is that Europe has loaned to these countries the capital with which to finance their enterprises, and trade follows the loan as

surely as night the day. The amount of money which Great Britain has thus loaned is estimated by Sir George Paish as follows:

	In 1913	In the past seven years	All told
Argentina	$ 93,205,000	$591,695,000	$1,600,000,000
Brazil	104,350,000	441,135,000	739,000,000
Chile	12,920,000	137,815,000	305,715,000
Peru	4,500,000	34,945,000	170,865,000
Others	7,195,000	55,640,000	180,620,000

A third reason why South American trade goes largely to Europe is that all the countries south of Colombia have been nearer Europe than they are to the United

MAP SHOWING RELATION OF NORTH AND SOUTH AMERICA.

States. North and South America lie *en echelon*, so that all South America is east of our Atlantic seaboard and all the countries on the east coast of South America are nearer Europe than they are to New York. When shipping had to travel through the Straits of Magellan to reach the west coast of South America, this was also true of the countries of the western seaboard; but now that the Panama canal is open, the reverse is true, and the Pacific ports of South America are about 3000 miles nearer to New York than to Europe. Until this year our banking facilities with South America were very poor, since our national banks were not permitted to have foreign branches; but this defect is now in process of being remedied, and the National City Bank of New York has been especially active recently in extending its South American connections, having already sent J. H. Allen, former manager of the Banque Nationale d'Haiti, and G. H. Colton, former governor of Porto Rico, to open a branch in Buenos Aires.

So much for general conditions. What chance is there for the sale of mining equipment in South America, and the sale of mineral products in the United States? South American countries obviously cannot buy largely in our markets unless they can also sell us their products, in order to establish a credit here.

Brazil

Beginning with the largest, it is well known that Brazil has a flourishing mineral industry. This country in area is 40% of all South America, and its population is 46% of the total. Unfortunately, it lies nearer Europe than it does to us, and also has utilized large amounts of European capital, wherein may lie the explanation that it sells us $141,000,000 worth of material each year and only buys $48,000,000 worth from us. Brazil has, therefore, the largest field for trade increase. Of the Brazilian gold mines, the Morro Velho, at Villa Nova de Lima, in Minas Geraes, is worked by British capital, and the Ouro Preto, at Passagem, is also. The Morro Velho has paid over $10,000,000 in dividends. Most of the Brazilian gold output comes from the state of Minas Geraes, though gold has been found and worked in nearly every state. The production of diamonds is also important in Minas Geraes, though much less so than in former years, the yearly output of diamonds being worth about $1,000,000. While North Americans are interested in the field, there is little chance of selling much equipment to the diamond miners, who use little beyond a crowbar, hammer, scoop, and a wooden *batea* in their operations. Larger scale working, such as dredging, has been tried, but the returns have not as yet justified the increased expense. There ought to be opportunity for the sale of equipment for the gold mines, however, especially if North American capital is forthcoming to develop new ones. Last year an engineer from the United States examined a large area in Minas Geraes in the interest of New York and Philadelphia investors, but difficulties arose regarding title, and nothing has yet been done. Greater possibilities exist in the iron ore deposits of the states of Sao Paulo, Minas Geraes, Santa Catharina, Esperito Santo, Bahia, Matto Grosso, Goyez, and Rio Grande del Sul. It has been estimated that the known ore reserves in Minas Geraes alone amount to 500,000,000 tons of ore averaging 50 to 70% iron. Experienced engineers from the United States have studied the field, and North Americans have acquired extensive holdings, as also have European investors. The St. John Del Rey Mining Co., owner of the Morro Velho gold mine, has extensive iron ore lands, but so far the lack of coal for smelting, and the high cost of transportation, have acted as a brake on active development. Manganese ore deposits exist in Minas Geraes, Matto Grosso, and Bahia, and the annual exports amount to 150,000 to 250,000 tons. The world is decidedly rich in manganese ore deposits, however, and the possibility of working any given deposit

is wholly dependent on commercial conditions, chiefly low freight rates. Monazite sand is one of the important products of Brazil and is mostly collected along the seacoast between Bahia and Rio de Janeiro. Monazite is so much in demand that it is quite possible that improved methods for its recovery would permit the establishment of a profitable industry. Deposits of zinc, copper, tin, lead, graphite, and coal are known to exist, but their exploitation is hampered by poor transportation facilities, railroads only having reached into the southern part of Minas Geraes, while Bahia, Matto Grosso, and Goyez are almost without railroads. Brazil is short of coal, importing about $20,000,000 worth per year, almost all from Great Britain. It also buys $5,000,000 worth of cement each year, chiefly from Germany and Great Britain. It buys about $50,000,000 worth of iron and steel manufactures each year, of which the United States furnishes a good part. Of locomotives and sewing machines, this country now furnishes more than one-half the Brazilian imports. Structural material and industrial machinery comes largely from Germany, rails from Belgium and France, tools and pipe come largely from Great Britain. The market for well-drilling outfits, water wheels, and turbines, dynamos and motors, etc., is good, and is growing. In railways, electric lighting, and power systems, American equipment holds a prominent place. In view of this, and of the huge size of Brazil, that country appears to be the best hunting ground for American firms looking for business. It must not be forgotten that the language of Brazil is Portuguese, and not Spanish as in other South American countries. Here as elsewhere throughout South America, business correspondence may usually be conducted in French without trouble.

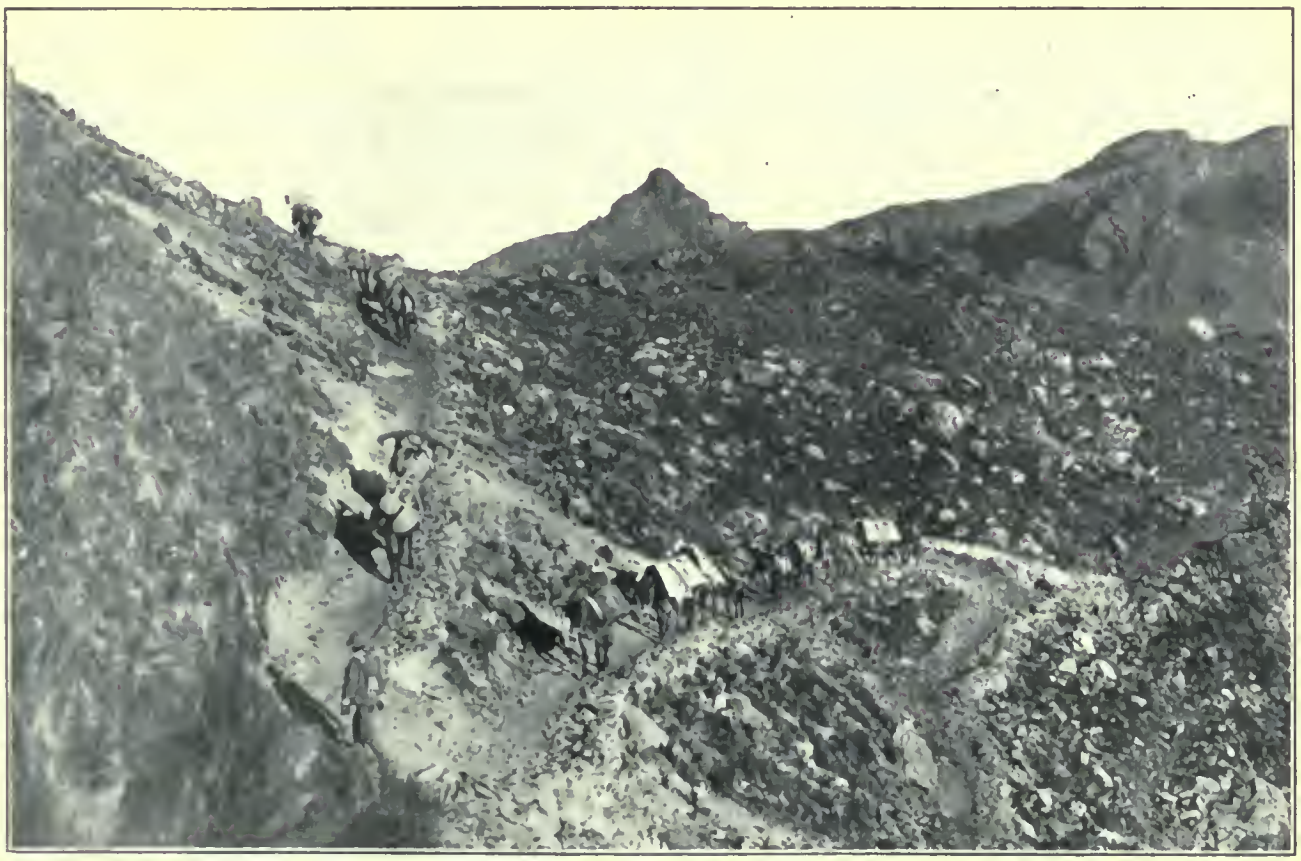
Argentina

Argentina has a much larger import and export trade, in proportion to its size, than Brazil. The reason for this is that it is less self dependent, producing mainly grain, meat, wool, and hides, importing the other articles of daily life. Much of Argentina resembles Kansas, Nebraska, and the Dakotas, and is correspondingly unpromising from a mineral standpoint; but back of these regions lie the Andes, of which the eastern slope belongs to the Argentine Republic. Lead, copper, antimony, borax, sulphur, and coal deposits are known to exist. These fields were studied for the Argentine government by I. C. White. Strong efforts have been made to develop coal mines as a domestic supply for the Argentine state railways, but coal imports are likely to continue to be important. Oil has been found at Comodora Rivadavia, on the coast 700 miles south of Buenos Aires, and every effort will be made to develop an adequate domestic oil supply. American enterprise in Argentina has had a strong asset in that Bayley Willis, formerly of the United States Geological Survey, has been serving as consulting geologist to the Argentine government in the development of its mineral resources in connection with the Argentine state railway system; of which nearly 4000 miles is now in operation, though not very successfully. There is over 17,000 miles of privately owned railway. As the capital with which these railways is being built is being furnished by British investors, it is natural that equipment is largely purchased from Great Britain. The United States is fifth in the list of countries selling goods to Argentina and seventh in the list of countries to which exports go. Except for hides and wool, we do not offer a market for the products of Argentina and are not prepared to buy much from that country in return for sales to it. Most countries buy their imports in the same markets in which they sell exports, and this, coupled with the large amount of European capital invested in Argentina, which usually carries with it some obligation to buy supplies of the European affiliations of the capitalists, makes it difficult to increase the trade with the United States. The foreign trade of Argentina is so large and our other advantages, already mentioned, are such that it is well worth while to direct efforts toward increasing our trade relations.

Bolivia

Bolivia is the next in size of South American countries and is the only one which has no seacoast, all her foreign trade passing through Chile and Peru. The foreign trade of Bolivia is small, only a tenth of that of Argentina, and the part of it falling to the United States is almost negligible, ranking eleventh in exports and ninth in imports. The reason for this is that over two-thirds of the exports of Bolivia consist of tin concentrate which is sent to Great Britain and Germany for smelting. Bolivia imports iron manufactures, cotton goods, sugar, machinery, coal, and a variety of other goods, and naturally buys them in the countries where she sells her tin and has credits. Bolivia is an undeveloped country with a sparse population, about one half of whom are Indians and almost another quarter mixed blood or *Cholos*. Mining conditions in Bolivia were discussed by Carlos Sanjines in our issue of March 9, 1912, while G. W. Wepfer has contributed a series of articles on Bolivia which have appeared at various times in the past year. F. C. Lincoln has also written of mining conditions in the country. The tin deposits of Bolivia have been described in detail by Mr. Wepfer and also discussed at length in our editorial columns. The yearly output of tin in Bolivia amounts to about one-half our imports of that metal, and if the smelting of Bolivian concentrate could be diverted to the United States, the credits thus established here would lead naturally to the purchase of equipment and other machinery in this country. The silver mines of Potosi are so well known as to need no further reference; after a long productive activity they are steadily waning. Copper is of considerable importance. Bolivia is the principal producer of bismuth, most of which comes from the Huayna-Potosi tin mines, near La Paz. Zinc, tungsten, and gold are mined, but the total output is small as yet. One great drawback to the development

of Bolivia is its lack of coal. Possible sources of hydro-electric power are abundant, and oil has been discovered in Bolivia, so that this power difficulty bids fair to be overcome. The country offers great future possibilities, but, excepting those in connection with tin, already mentioned, not much immediate returns as a trade field. The interest of the United States in Bolivia is steadily increasing. H. G. Knowles, till recently American minister to the country, is president of the Bolivian Development & Exploration Co., which is financing and developing a number of properties.



PACKING EQUIPMENT TO THE INCAORO MINE IN BOLIVIA.

Peru

Peru is another big country with a comparatively small foreign trade, in which mineral products are the leading exports. The total output of copper in Peru was over $9,000,000 in 1912, and of silver $5,000,000 in the same year. The copper was exported for refining, but most of the silver remained in the country. The mines and smelters of Peru were described in some detail by Howland Bancroft in our issue of January 25, 1913, page 173. General conditions in Peru were described by Pierre Bonery in our issue of June 14, 1913, page 890, and prospecting conditions in Peru were described by C. S. Haley and C. A. Rodegerdts in that of December 13, 1913, page 922. Spencer Bishop described the Cerro de Pasco smelter in January 24, 1914, page 177, while Lester Strauss reviewed the preceding year's progress in mining in Peru March 21, 1914, page 482. The opening of the Panama canal renders Peru one of the most accessible, instead of the most inaccessible of South American countries, and with the improved banking facilities now becoming available, there should be considerable increase in our trade there.

Chile

Chile has a tremendous export trade, in proportion to its size, because of its shipments of sodium nitrate and copper, which go mostly to Great Britain and Germany. Cotton goods, manufactures of iron and steel, and coal are its principal imports, though it buys a wide variety of products. Cotton goods and coal come mostly from England. The United States has a fair share of the trade in iron and steel manufactures, and supplies nearly all the crude petroleum, refined petroleum products, and lumber. The mineral deposits of Chile were discussed in detail by Juan Blanquier in our issues of March 29, April 5, and April 19, 1913. The nitrate fields of Chile were described in detail by S. H. Loram in our issues of January 15 and 29, 1910, and further discussed by Walter S. Tower September 27, 1913. They were recently reviewed by Lester W. Strauss in the issues of June 13, June 20, and June 27, 1914. The iron ore deposits were described by Carlos Vattier in our issue of December 6, 1913, and the development of hydro-electric power in Chile and Peru was discussed by Lewis R. Freeman, February 21, 1914. Numerous other articles on Chile have appeared in our columns

in the past year. The copper of the Braden mine which formerly went to Europe for refining has recently been diverted to Baltimore. The great developments of the Chile Copper Co. at Chuquicamata, illustrated on our cover this week, presage what is possible by joining North American money and technical knowledge to South American opportunity. We printed April 4 a review of progress at this great mine by Daniel Guggenheim, and May 2 an account of the leaching process that is to be used, written by E. A. Cappelen Smith, the metallurgist. Regular shipments to this country of the iron ores owned by the Bethlehem Steel Co. in Chile will soon be made. This increasing stream of trade with Chile, together with the improved banking facilities now afforded, should lead to rapid growth in other lines of trade.

Ecuador

Ecuador is the smallest of the countries on the west coast of South America, having an estimated area of 116,000 square miles and a population of 1,500,000, of whom only 100,000 or 200,000 are whites. Guayaquil, the chief seaport, and Quito, the capital, are the only two cities of over 50,000 inhabitants. The government of Ecuador has arranged to spend $10,000,000 in improvement of the port of Guayaquil and J. G. White & Co. has the engineering work under construction. With these improved facilities the trade of the country will probably increase largely. The geology of Ecuador was described by W. A. Wolf in our issue of July 27, 1912. Of the known metal deposits, the gold placers are the only ones that have been worked to any extent, about $300,000 worth of gold being exported yearly. The principal quartz mine, owned by Americans, is at Zaruma. The petroleum deposits are very promising, as fuel is scarce along the west coast of South America. Deposits of copper, iron, silver, lead, coal, and sulphur are reported, but comparatively little is known about them.

Uruguay

Uruguay is only one-half the size of Paraguay, but has nearly double the population and has ten times the foreign trade. It is chiefly a pastoral country and exports wool, sheepskins, and hides in large amount, taking in return as imports sugar, coal, beverages, and all kinds of manufactured products. It is therefore a good country to trade with. There is a good deal of capital invested in gold mines, but the ventures have mostly not been very profitable as yet. A great variety of mineral products is worked, the total output in 1912 being valued at $3,000,000. A note in regard to the mineral deposits of Uruguay appeared in our issue of September 14, 1912, page 332.

Paraguay

Paraguay, which is generally associated in the public mind with Uruguay, has about double the area of the latter and only about one-half the population, having lost about half its people in the war waged between 1865 and 1870 with Argentina, Brazil, and Uruguay. The country is divided into two nearly equal parts by the Paraguay river, the western half being a low lying plain which is almost unexplored. The eastern half is rolling country, the ridges being less than 2000 ft. high. The foreign trade is small and is principally with Germany and Great Britain, imports from the United States amounting to less than $400,000 per year, chiefly hardware. When developed, Paraguay will probably have large exports, but there does not seem to be much likelihood that it will ever be an important mining country.

Colombia

Colombia also has comparatively little foreign trade. With a range of climate from a tropical seacoast to high cool plateaus, it is able to produce within its borders most of the things it needs. Coffee, hides, and bananas are the principal exports; textiles account for one-half of the imports. Gold production in Colombia has been the subject of many articles in our columns. The petroleum deposits of Colombia assumed international importance last year. The iron ore deposits are notable, and efforts are being made to build up a domestic iron industry. Coal deposits are numerous and will doubtless be extensively worked later. Copper deposits are of wide distribution, silver production amounts to $500,000 to $750,000 annually, and an equal amount of platinum is produced on the west coast; emeralds are an important mineral product. A good deal of the capital engaged in mining is British, and there will be more unless it is possible to secure money in this country. Colombia is so easy of access from this country that it deserves more attention than it has been receiving, practically all the American capital invested there being in gold mining.

Venezuela

Venezuela is much like Colombia in many ways, but has suffered at times from poor government, which has retarded the development of the country. Copper, *balata*, cacao, and hides make up most of its exports. Cotton goods from England and flour from the United States are its principal imports. Gold production was once important, especially in the region south of the Orinoco, but has declined; the easily accessible deposits have been worked out, and lack of means of transport prevents easy access to the others. Iron ore is mined at Imataca by a Canadian company which ships the ore to Philadelphia. Coal is mined near Barcelona, and other deposits exist. Asphalt is produced on Lake Maracaibo and on the San Juan river. Prospecting for oil is in progress. Some copper mining is done, and the South American Copper Syndicate, an English company, with mines near Aroa, pays good dividends.

Nicaragua

Nicaragua, Guatemala, Honduras, and Cuba are four countries of nearly the same size, but greatly different in population, as Nicaragua has only one-fourth the population of Cuba, and less than one-fiftieth its foreign

trade. The mining industry of Nicaragua has been so frequently and fully described in the columns of the *Mining and Scientific Press* that it is unnecessary to review it here. The best known district is the Pis Pis, which was fully discussed in our issue of February 17, 1912, by Oscar S. Hershey. In the issue of August 12, 1911, T. Lane Carter writes on the mining possibilities of Nicaragua, and in the issue of December 7, 1912, Arthur Feust describes the Chontales mining district. H. B. Kaeding gave valuable data on operating costs, October 28, 1911. In our issue of January 6, 1912, T. Lane Carter reviewed the progress in Nicaraguan mining for the preceding year. Other articles are those by W. A. Connolly, March 5, 1910, and September 21, 1912. The Deitrick concession was discussed February 21, 1914, p. 332, and the Eden Mining Co., controlled by the Tonopah Mining Co., February 21, 1914, p. 352. The most important group of mines is that controlled through the Canadian Agency by the Camp Bird, Ltd., discussed December 27, 1913, p. 1033.

PASTO, COLOMBIA, ONE OF THE DELIGHTFUL SMALLER CITIES OF SOUTH AMERICA.

Guatemala

Guatemala, which is separated from Nicaragua by Honduras and Salvador, has three times its population and nearly four times its foreign trade. Fruit, sugar, coffee, rubber, and timber are the principal products, and the country is a good one to do business with in that its exports are, in value, about four times its imports. January 6, 1912, T. Lane Carter discussed mining in Guatemala, which has not been greatly developed as yet.

Honduras

Honduras is almost the same size as Guatemala, but has only one-fourth its population, and of its 500,000 people the majority are Indians. The country is comparatively undeveloped and has a public debt of nearly $30,000,000, the money having been borrowed over 40 years ago to build an inter-ocean railway, but it was mostly spent for other purposes. The country is rich in agricultural and mineral land; most of its exports are agricultural products and timber. The mineral wealth of the country is apparently great; the best known mines are those of the New York & Honduras Rosario Mining Co., to which frequent reference has been made in these columns. The new 20-stamp mill was described by R. B. Rogers, March 29, 1913; it was also described in the issue of December 14, 1912. Nearby is the tract of the

Antigua Gold-Copper Co., which is developing deposits of copper ore, containing gold and silver, in limestone. To our issue of July 12, 1913, A. D. Akin contributed an intensely interesting account of the gold placers and other mineral deposits of the Olancho Mountain region. Mining progress in Honduras in 1911 was reviewed by T. Lane Carter, January 6, 1912.

Cuba

Cuba is about the size of each of the three preceding countries, but has a population about equal to all theirs combined and a foreign trade equal to ten times their combined trade. Because of its output of tobacco and sugar Cuba has always had considerable foreign trade, but this has greatly increased since 1900, when a stable form of government was set up under the suzerainty of the United States. This is doubtless indicative of the progress which is likely to be made by the other Central American republics when more stable governments are established. The iron mines of Cuba, chiefly owned by the Spanish-American Iron Co., are well known; in our issue of August 8, 1914, C. F. Rand, the president of the Company, described the sanitation work at these properties, and the method of mining the ore was described in our issue of October 4, 1913. El Cobre mines, near Santiago, now owned and operated by the Cuba Copper Co., were the first copper mines worked in the new world, having been opened in 1532. The flotation plant at these mines was described in our editorial columns, May 24, 1913. Cuba offers much promise of mineral production, but capital has so far found such profitable fields for investment in agriculture that mining has as yet been less developed.

Panama

The recently constituted republic of Panama is a little smaller than Honduras and has about the same proportionate population. Just now, for obvious reasons, the import trade of Panama greatly exceeds the exports. The gold mines of the isthmus of Darien have been famous ever since the Spaniards began to traverse the isthmus on their way to and from the west coast of South America, but their fame exceeds their real importance. The methods of working at the Darien mine, which was very profitable, but is now nearly worked out, were detailed in our issue of August 24, 1907, by A. B. Chase. Altogether about 170 mining properties have been denounced by mining companies, covering such a wide range as gold, silver, copper, iron, sulphur, asbestos, and limestone. Under the steadying influence of the United States, Panama seems likely to exhibit as rapid progress as any South American country.

Costa Rica

Costa Rica, adjoining Panama on the north, is somewhat smaller, but has almost exactly equal population. The mineral resources of the republic were interestingly described by Lee Fraser, January 21, 1911. The best known mines are the Abangarez and the Montezuma. Cyanide practice at the latter was discussed by F. S. Shaw, January 28, 1911. The Abangarez company has a hydro-electric plant and has spent much money on improving its property, so although the mill has been producing about $20,000 per month in bullion this has been expended in betterments. La Union Mining Co. is another producer. Gold and silver exports from Costa Rica are over $1,000,000 per year, and the stable political conditions which exist there make the region attractive to investors.

Santo Domingo and Haiti

Santo Domingo and Haiti can well be considered together, since together they form an island and exhibit similar political interest. Santo Domingo is nearly double the size of Haiti, but has only one-third the population of the negro republic. In Santo Domingo there are promising mineral areas which have attracted attention almost continuously during the past 40 years. Unfortunately they have been made the basis for scheme after scheme by the jackals of mining. In our issue of February 14, 1914, J. W. Ledoux described some of the more recent of these unsavory ventures. To the issue of September 7, 1907, F. Lynwood Garrison contributed a paper on the sulphide ores of the San Christobal district.

Haiti is a less attractive mining field than Santo Domingo in that political conditions are less stable and the mineral areas seem less promising. An exploration syndicate did considerable work in Haiti about ten years ago, and the Cia. Miniére de Terre Neuve is now attempting to develop a copper mine. There is no present production.

Salvador

Salvador is the smallest of the countries of South and Central America, but by no means the least important from a mining standpoint. Though smaller than the state of New Jersey, it has a larger foreign commerce than any of the immediately adjoining countries and boasts of several valuable mines, and an annual gold and silver output of about $1,500,000. The Butters Salvador mines are the best known; others are the Los Escuentros, El Tobanco, Comacaran, and Monte Mayor. Salvador is more thickly settled and has been more thoroughly prospected than have the adjoining regions.

Mexico

During the past three years there has been a general decline in all branches of trade with Mexico, and due to the unsettled conditions it has not been possible for the central government to compile detailed statistics covering this period. The imports and exports from Mexico have been, however, of primary importance to the American producer and manufacturer, for in addition to being our nearest neighbor it affords one of the largest marts for trade in the western hemisphere. The figures for the fiscal year 1911-12 are the last general compilation available and are fairly representative of a normal year, although showing a decrease in imports of about

₱20,000,000 from the preceding year. The figures presented in the following table for 1910-11 and 1911-12 may be considered the last two normal years of trade, and in this last year, 1911-12, will be noted a general decline which has consistently continued since that time.

	1910-11	1911-12
Animal products: including live-stock, hides, meats, furs, manufactured materials, etc.	₱17,433,251	₱16,466,311
Vegetable products: including textile fibres, fruits, grain, lumber, manufactured products, etc.	38,600,222	31,285,563
Mineral products: including gold, silver, copper, lead, zinc, tin, iron, stones, earths, etc.	52,030,587	46,711,978
Textiles and manufactured products: including cotton, linen, wool, silk, etc.	24,640,269	21,281,571
Chemicals and drugs	12,990,250	12,074,088
Fermented and unfermented liquors.	6,813,346	6,744,083
Paper and paper products	5,608,939	5,120,770
Machinery and apparatus	25,811,176	23,383,811
Vehicles	9,095,206	4,600,890
Arms and explosives	3,212,567	5,388,344
Other products	9,638,455	9,604,897
Total imports	₱205,874,268	₱182,662,306

It will be seen that there has been a general decrease in all branches, with the exception of arms and explosives—evidence of the beginning of revolutionary activity. While the figures quoted are in pesos, it must be remembered that foreign trade is practically all done on a gold basis, and the exchange at the time of this compilation was about 50, or two for one (at the present it has fallen to 20, and it, therefore, is doubly necessary that all manufacturers make their quotations in American currency and f.o.b. factory, in the event of their not keeping stocks in Mexico).

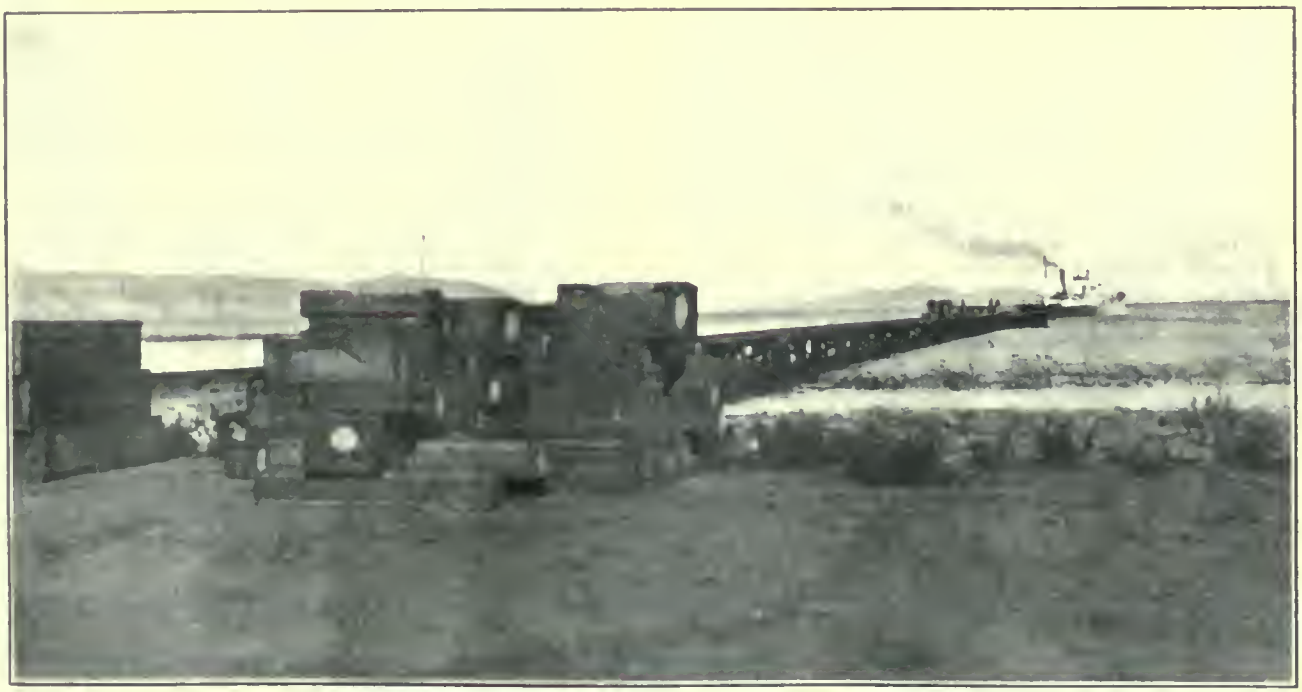
The distribution of this import trade with various parts of the world during these two years has been as follows:

	1910-11	1911-12
Europe	₱86,469,309	₱78,171,459
Asia	3,142,661	3,047,939
Africa	307,813	111,722
North America	113,916,705	99,390,251
Central America	195,424	98,290
South America	1,492,923	1,576,194
Antilles: including Barbados, Cuba, Haiti, Jamaica, Porto Rico, Santo Domingo, Trinidad, etc.	203,278	163,969
Pacific Isles: including Australia, Borneo, Philippines, Hawaii, etc.	146,155	102,545
Total	₱205,874,269	₱182,662,369

The imports from North America were divided as follows:

Canada	₱ 769,722	₱ 964,578
United States	113,146,983	98,425,673

It is evident from the above figures that the United States has had a large percentage of the Mexican trade in the past, but it is also to be noted that there is a large percentage of the imports, amounting to ₱78,171,459 in 1911-12, which were supplied by the European market. With a revival of industry in Mexico, which now seems highly probable, a large part of this trade can be met by American producers, since European trade has been so seriously crippled.



LANDING FREIGHT FOR BOLIVIA AT LAKE TITICACA, PERU.

The export trade of Mexico is of course largely of mineral products; out of a total of ₱297,989,129 of exports during the fiscal year 1911-12, ₱186,206,803 was the value of the products of the mines. An analysis of these figures shows that the United States is the recipient of a very large part of the Mexican exports, the exports for 1911-12 to this country amounting to ₱224,103,220.

The division of Mexico's export trade for the last two normal fiscal years, 1910-11 and 1911-12:

	1910-11	1911-12
Europe	₱63,296,542	₱68,159,099
Asia	40,012	18,192
North America	226,334,110	225,459,911
Central America	1,802,770	2,157,655
South America	69,374	66,443
Antilles	2,210,831	1,958,011
Pacific Islands	.....	169,818
Total	₱293,753,639	₱297,989,129

With the reëstablishment of peace, resumption of railway traffic, reopening of the mines and *haciendas*, toward which there is an undoubted tendency at the present, Mexico bids fair to again become a factor of importance in our export trade and is well worth study and consideration.

The Incaoro Mill, Bolivia

By R. B. T. KILIANI

The mill of the Incaoro Mines Co. at Pallaya near Yani, in the district of Larecajas, department of La Paz, Bolivia,* is of interest as illustrating some of the difficulties to be overcome in the operation of mines in the interior of South America. Owing to the fact that all machinery has to be taken into the mine, 120 miles, from the head of Lake Titicaca, on mule-back, over a pass about 16,500 ft. high, it was necessary that it should all be sectionalized to a limit of 350 pounds. Some of the difficulties of transportation are shown in the illustrations, pages 795 and 799, showing the landing of material on the shore of the lake and packing it up to the mine.

The ore from the mine is lowered to a stone storage bin by an incline gravity tram and is then taken to the mill in small hand trams as required. The power plant is a 24-in. sectionalized Pelton wheel belted to a line-shaft running the length of the mill. Ore from the tram is delivered to a Buchanan jaw-crusher, thence into a mill-bin, from there into a 4½ ft. by 13-in. sectionalized Hardinge ball-mill from which it is passed to a 6 ft. by 22-in. sectionalized Hardinge pebble mill.

The recovery is by amalgamation only, partly inside the two mills and partly on outside plates. Mercury is fed in at the head end of the ball-mill, amalgamated in this machine, and passes through to the pebble mill, which catches the greater portion of the coarse gold. The machines are shut down once a day to make a clean-up of the amalgam in the mills, from which approximately 75% of the total recovery is made. The amalgam in these machines is very hard, containing slightly over 50% gold. This is attributed to the fact that the pounding of the balls and pebbles in the mills squeezes out all the free mercury, leaving a very hard amalgam which balls up and tumbles around. The other 25% of the recovery is made on two sets of plates below the pebble mill. The ore milled per day amounts to about fifty tons.

The labor is entirely native, about one hundred Indians being employed: the wages vary from 16c. for boys to $1.60 for mine captains. The mill itself is operated by two men, each receiving $1.40 per day. One of these men attends to the feeding of the ore from the mill-bin and such other work as is required on the lower floor, the other man attending to the crusher. This makes the milling cost about 15c. per ton, as water-power is used, and the repairs are very light.

The Hardinge mills were both sectionalized to a maximum of 350 lb. and were assembled and set up according to marking and instructions from the factory. The ball-mill is lined with chrome steel plates and uses forged steel balls for grinding, as it has been found that it is cheaper to import this material from the United States than to purchase cast iron in La Paz. The pebble mill is lined with quartz bricks about 6 in. thick, which are roughly chipped to size on the property. These bricks are fastened in the machine, without any cement being used, by means of dry wooden wedges which swell in operation and hold the lining tightly in position. Danish pebbles were first tried for grinding in the pebble mill, but it was later found that hard quartz roughly chipped to spherical form proved cheaper, owing to cost of transportation.

*For description of the mine by F. C. Lincoln see *Mining and Scientific Press*, April 4, 1914.

HARDINGE MILL AND PLATES AT INCAORO.

PELTON WATER-WHEEL AT INCAORO.

Hydraulic Stowing in the Gold Mines of the Witwatersrand

By B. C. GULLACHSEN

*Hydraulic stowing of mine workings is a subject that is coming more into prominence. As is well known, Upper Silesia receives the credit of being the birthplace of hydraulic stowing. Even if it had been employed on a small scale at a previous date in other parts of the world, it remained for Herr Bergrat Williger to introduce it on a large and economic scale at the Myslowitz mine in Upper Silesia during the year 1901. In Upper Silesia at the present time no less than 30 collieries, employing 48 separate plants, out of a total of 58 collieries, have adopted hydraulic stowing.[1] In Westphalia the system is also extensively employed, and no doubt would be more so if it were not for the difficulty of securing suitable stowing material. During the year 1909 H. C. Annett read a paper before the Institute dealing with hydraulic stowing in Westphalia, in which a full description of the plant, together with costs, is given.[2] In Westphalia 27 collieries, employing 40 equipments, use the process daily. In Prussia, the method is employed in the iron, potash, and salt mines, as well as at the Saint Ingbert collieries in Bavaria. In Alsace Lorraine a plant is at work in the district of Petite Rossette. Outside Germany the hydraulic process of stowing is also widely utilized. In France it has been considerably used, especially at the collieries in the Department of the Pas de Calais, and also in the coalfields of St. Etienne. In Belgium it is also used at several collieries. L. D. Ford recently communicated a paper to the Institute dealing with hydraulic packing of the goaf in Belgium.[3] In Spain the Penarroza colliery is erecting a plant, and several collieries in Austria, as well as in Poland and Russia, are employing the system.

Hydraulic stowing is extensively used at a number of mines in the United States, at lignite mines in Manchuria, and in the gold mines of Australia and the Transvaal. In the Transvaal hydraulic stowing was first used in the gold mines about the middle of 1909, but credit is often given to the late President Kruger for having several years previously suggested that the unsightly residual sand dumps, which were then commencing to make themselves objectionable, should be conveyed underground to fill up the excavated portions of the mine.

The first mine at which hydraulic stowing, or 'sand filling,' as it is more generally called on the Rand, was commenced was the Village Main gold mine, to be followed shortly afterward by the Ferreira gold mine, and by June 1910 the Village Main was sending underground about 1200 tons of sand per day. During 1911 several more mines were equipped, and in the annual report of the Central Mining & Investment Co. for 1912 it is stated that at seven mines of this group alone 984,650 tons of sand was stowed into the worked out stopes. At the present date 15 mines on the Rand have erected hydraulic equipment, and more are to follow in the near future.

Hydraulic stowing on the Rand may be divided into two systems, namely: (1) sand taken from dumps; and (2) sand taken direct from the cyanide vats. In the first of these two systems the sand to be used for stowing is taken from the mine dump (the dump consisting of the residual sand after the gold has been extracted). The following description is that of the sand-filling arrangements employed at the Geldenhuis Deep gold mine, Fig. 1.

Sand filling at the Geldenhuis Deep gold mine.—The sand at the dump is shoveled into trucks, which are then taken by an endless rope haulage to the collecting bins, situated near the entrance to the mine. The sand is tipped into these bins, which are furnished with sliding doors, through which the sand is made to pass when required. Projecting through these doors are short lengths of 3-in. piping, having a flat shaped nozzle end, and perforated along its length with small holes. Water under pressure is turned into this pipe, and is injected into the surrounding sand, which is then washed through the doors into the launder. In the event of the sand coming through too thickly, more water may be added in the launder from the water pipe provided for that purpose at the end of the launder. The pulp flows down the launder, which has a gradient of about 15°, into a box shaped receptacle at the top of the shaft, from which box the pulp is conveyed through 6-in. cast iron pipes to its desired destination underground.

At the Robinson gold mine the arrangements are different, as at this mine the dump was so conveniently situated to the mine workings that it was found unnecessary to convey the sand to storage bins. The sand is washed direct from the dumps by means of high-pressure water thrown upon it by hydraulic monitors with 3-in. nozzles, which force of water breaks into the dump and washes the sand away into launders. The pulp then proceeds direct into a small shaft, from the bottom of which the pulp is conveyed into the workings by means of launders.

*Abstract of a paper read before the North of England Inst. Min. and Mech. Eng. and printed in the *Trans.* Inst. Min. Engineers.

Unless, as in the case of the Robinson mine, the sand can be washed direct into the workings from the dump, this system has the disadvantage that the sand must be shoveled from the dump into trucks and then conveyed to the collecting bins, an expense not incurred by the other system. When sand from old dumps is used, considerable quantities of lime must be added in order to neutralize the sulphuric acid formed by the decomposition of the pyrite. Another disadvantage of using old dump sand is that the sand is mixed with a considerable quantity of colloidal slime, the presence of which is very objectionable underground.

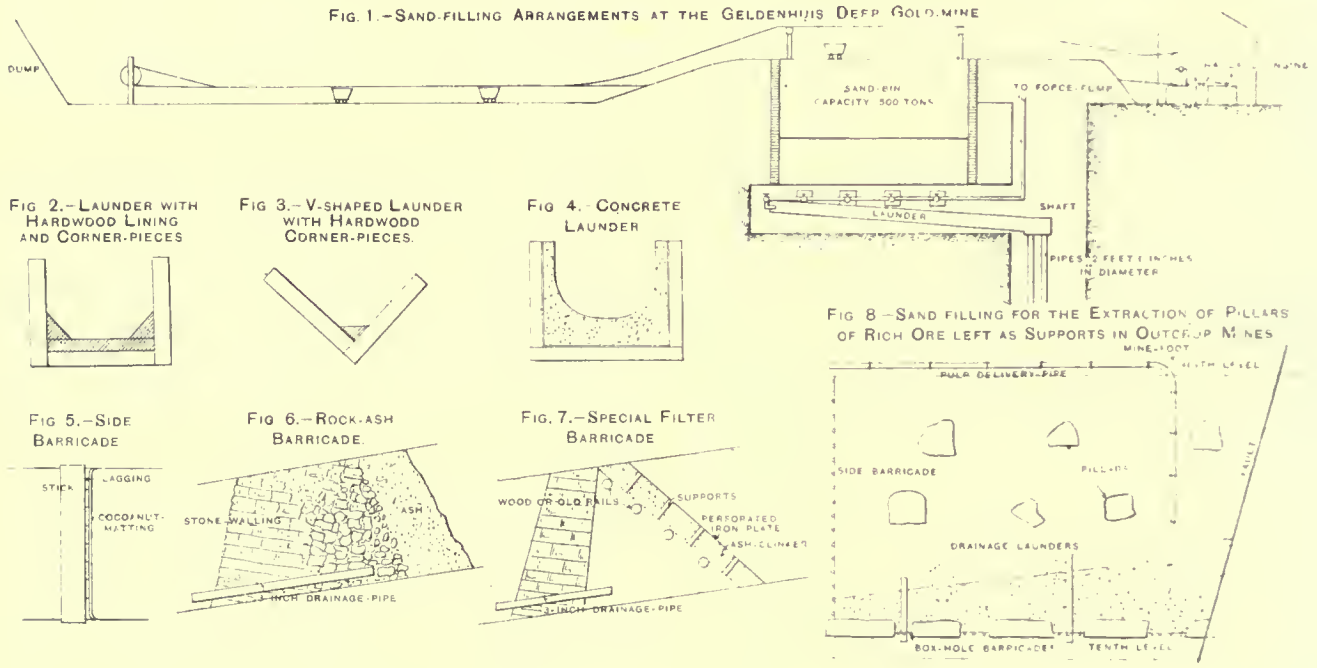
Sand taken direct from the cyanide vats.—This system was first employed on a large scale at the Simmer and Jack mine, although current sand residue had previously been employed to some extent at the City and Suburban mine.

The essential feature of this system consists of using the sand as soon as it is discharged from the cyanide vats, thus doing away with the cost of transporting it to the top of high dumps, whence, as in the first system, it has again to be shoveled into trucks and transported to the collecting bins. What was at first looked upon as a grave objection to this system was the presence in current sand residue of dangerous quantities of potassium cyanide, and it was found to be absolutely necessary to destroy the cyanide before the sand could be used. This was accomplished by introducing into the water a small amount of permanganate of potash solution. The residue pulp should be kept alkaline, so as to assist the oxidizing effect of the permanganate. The consumption of permanganate may vary from 0.04 to 0.08 lb., which is equivalent to about ¼d. to ½d. per ton of sand used. According to the Mining Regulations, no solution containing more than 0.005% of total cyanide may be sent underground. The tests for such small quantities are naturally very delicate operations, but those employed by A. McA. Johnston have proved perfectly satisfactory.[4]

In this system it is a great advantage if the sand-treatment vats are situated so that the sand immediately on being discharged can be mixed with water and permanganate and run directly into the mine. As frequently occurs, the vats are placed some considerable distance from the bore-hole or entrance to the mine, in which case, as at the Simmer and Jack, the pulp has to be pumped to the position where it is required. The pulp then passes through dewatering cone classifiers, the underflow from which is then discharged into the bore-hole or pipe-line leading to the mine workings, while the overflow runs or is pumped back to the mixing bin, when it is again utilized to bring up more sand.

It is interesting to note that in this system the ore hoisted from the mine about a fortnight previously is returned again minus its gold content, and that a ton of the ore which occupied a space of 12 cu. ft. *in situ* in the mine yields about the same volume of sand for return underground, after the ore has been well crushed and classified into 50% sand and slime, respectively.

Conveyance of the sand down the mine.—There are two methods of doing this, namely: (1) by means of pipes, and (2) by means of bore-holes. In the first case the pipes are hung in the shafts, care being taken to make them secure, on account of the considerable vibration caused by the passage of the thick pulp through them. The pipe-line must also be easily accessible, so as to allow of the easy and rapid removal of the lengths of pipes that become worn through. A great objection to the sand-filling pipe-lines being placed in the shaft is that, in the event of a pipe becoming



[4] 'Rand Metallurgical Practice,' Vol. I, p. 324.

worn through, or bursting, a considerable quantity of pulp is discharged into the shaft, causing a very objectionable mess.

It was at first considered that bore-holes would be impracticable, on account of their becoming choked, but in practice this is not the case if the bore-hole is of a reasonably large diameter. Bore-holes 7 or 8 inches in diameter have been found to give little trouble through choking. If a bore-hole should become choked, it can be cleared by running a small amount of water into it for a few hours.

Bore-holes have the great advantage over pipe-lines that after once the first cost has been met, there is no upkeep cost, as in the case of a pipe-line. There is also the additional advantage that they can be put down at the best point for the distribution of the filling material underground, thus avoiding in many cases the great lengths of more or less horizontal piping necessary when the pipe-line is taken down the shaft, and which are so liable to become choked.

Bore-holes are in use at the Simmer and Jack and Robinson Deep mines; that at the Simmer and Jack was put down by means of a jumper drill at a rate of 8 ft. per day, and at a cost of 17s. to 20s. per foot. The Robinson Deep bore-hole was bored by a steel shot drill to a depth of 1700 ft. in nine months, and cost £2625, or a little over 30s. per foot. The bore-hole at the Simmer and Jack mine has now been in use for four years, and no trouble has been experienced.

After the stowing material has reached the bottom of the shaft or bore-hole, the next consideration is the method to be used for its distribution underground. For this purpose, two methods are employed, namely: (1) by transport under pressure in pipes, and (2) by transport in launders. Transport under pressure in pipes is necessary in all mines when the filling material has to be conveyed along roads that are either horizontal or that only slightly dip or rise, the pressure being obtained by the head of pull on the vertical pipes in the shaft.

As there is naturally heavy wear and tear upon the lining of the pipes, many methods have been devised for their protection. In Germany pipes are manufactured with porcelain, wood, glass, and detachable steel linings. Oval pipes are used having half-oval liners bolted into them.

On the Rand, only three kinds of pipes have been used, the ordinary cast iron pipe, wood-lined pipes, and, to a very small extent, porcelain-lined pipes. The pipe-line is laid either along the foot of the drifts and stopes, or, when this is not practicable, the pipes are hung from the 'hanging' by means of chains attached to eye bolts, or else they are supported on timber trestles. The pipes may have loose or fixed flanges, rubber (insertion) washers being placed between them. After a few months' use the pipes are given a turn, in order that the bottom segment of the pipe, where the greatest wear takes place, may be replaced by a portion of the pipe which has suffered comparatively little damage through the abrasion of the sand particles. By this means the pipes can be used for a considerable length of time. The life of the pipes used on the Rand appears to be very variable, and it is therefore difficult to give any exact figures on this point.

Transport in launders is preferable to that in pipes wherever the gradient is suitable. The gradient required is dependent not merely upon the size of the sand particles and the ratio of sand to water, but also upon the volume of pulp and the roughness and internal shape of the launder. In a wooden launder, pulp containing 30% of moisture will flow slowly on a grade of 30%, approximately 17°; with 40% moisture on a 20% grade, approximately 11°; and with 60% moisture on a 10% grade, approximately 6 degrees.

Launders are made up of planks, the bottoms being provided with a liner of hard wood and with angle-pieces of hard wood in the corners, as shown in Fig. 2. V-shaped launders (Fig. 3) are easy of construction, cheap, and, being light, are useful when frequent replacement is necessary. At the Robinson mine, launders having concrete liners (Fig. 4) were used. These were made in 3-ft. lengths and placed inside the wooden launders. Drainage launders are used for carrying off the water from the surface of the filling. These launders are in box form, and must be of fairly strong construction in order to withstand the pressure of the filling material down through which they pass. Fresh lengths are added as the filling rises, each length provided with some means of escape for the water as it rises along its entire length. Either holes are drilled or the top plank is left off and short lengths nailed on as the water rises, cocoanut matting or wire netting being placed over the openings for the purpose of clearing the water.

Barriers.—Before filling can take place underground, the place which it is desired to fill must be prepared for the purpose. Wherever possible, faults, dikes, or portions of unprofitable bodies of ore are used as natural barriers; but as in many mines these natural barriers do not exist, or, as is more often the case, do not occur in that portion of the mine where they could be made use of, it is necessary to build artificial barriers.

Barriers should be built with two purposes in view—first to hold the sand in the position required, and second, to allow of the drainage of the water. The first barriers built underground on the Rand were constructed as water tight as possible, all the water being carried off from the surface of the filling by means of special drainage launders, which passed down through the sand and barriers, and were gradually lengthened as the sand was filled in. It is now found to be preferable to drain as much water as possible through the barriers, which must therefore be constructed to act as a form of filter-bed. Draining the water off directly through the barriers naturally reduces the pressure upon them to a very considerable extent, with the result that they need not be of such heavy construction as previously.

A barrier which has given good results, and does away entirely with the use of timber, is one built up of waste rock in the form of a pack. The outer wall is first built of large stones, and on the inside of this smaller stones are used, gradually decreasing in size until sufficient thickness of barrier has been constructed, ash being last of all thrown on. Such a barrier is shown in Fig. 5, and, if well constructed, will retain all the sand and only allow practically clear water to pass through it.

Several types of timber barriers have been used, all somewhat similar in construction, only differing slightly as to their method of drainage. Fig. 6 shows a barrier suitable for supporting the sides of the sand-pack, and consists of props set from 4 to 6 ft. apart and hitched at the bottom and the top. On the inside of the props either pitch pine or blue gum planks are nailed. The top and bottom planks are scribed to the roof and floor, and hay is often used to fill up any remaining openings. Cocoanut matting may be nailed to the planks, so as to act as a filter for the escaping water. Fig. 7 shows a barrier which is intended for use in a narrow opening, such as a box hole, and should only be used at the lowest point in the portion of ground that is to be filled. As will be seen, its object is to act as a filter-bed; ash is used as the filtering medium, and the filtered water is conveyed through the stone-pack by means of a 3-in. pipe.

Hydraulic stowing in deep mines.—When sand filling was first introduced on the Rand, it was only employed at the outcrop mines, in order to permit of the extraction of valuable pillars of rich ore which had been left as supports (Fig. 8). As time went on, sand filling was carried on at greater depths, and in the very deep mines it is especially necessary on account of the great roof pressure.

When filling takes place at a depth of from 3000 to 4000 ft., a heavy charge is incurred for pumping all the extra water introduced into the mine with the stowing material from this depth, as well as the extra cost for pipes due to their rapid destruction, caused by the high pressure and velocity of the pulp. In order to avoid these extra costs, a system was introduced at the Cinderella Deep mine, by which the sand was sent into the mine in a dry condition. In order to effect this, a wooden box launder was constructed measuring 12 by 11 in. inside cross-section. This launder was carried down the vertical shaft to the level at which the filling material was required, which was at a depth of 3900 ft. The sand, which should not contain more than 7% moisture, is stored in a surface bin, from which it is taken on a conveyor-belt to the top of the shaft and there discharged into the launder. On reaching the bottom of the launder, it falls upon a steeply inclined iron plate, at which point jets of water are turned into the sand, which is then carried away as a pulp either by means of pipes or by launders to wherever it may be required.

The great objection to this system is the difficulty of securing a constant supply of dry sand. As soon as the sand contains more than 7% of moisture, it is inclined to adhere gradually to the sides of the launder, which in time becomes choked. The launder was connected up to a Roots blower and jets of compressed air introduced, the idea being to assist the drying of the sand and to increase the velocity of the falling stream, but this device was found to result in only a very slight improvement. The system has much in its favor, but unless some method can be devised to enable sand containing more than 7% of moisture to be used successfully, it is certain to be a failure.

Drainage.—The clarifying of the overflow water before pumping is a matter of some importance, as, of course, water containing only a small percentage of sand and slime is injurious to the pumps. At those mines where old dumps are being used for filling, trouble is experienced with the large quantities of slime present with the sand. Great difficulty is found in getting the slime to settle, and on this account the use of current sand residues is much to be preferred. Slime has also the additional objection that it prevents, to a considerable extent, the rapid filtration of the water, on account of its forming a fairly impervious covering on the filter-bed at the barriers.

All the water overflowing from the sand filling is made to pass through the catch pits and filter-beds constructed in old drifts or stopes. The catch pits and filter-beds should always be constructed in duplicate, so that, in the event of one becoming filled up with sludge, the water may be turned into the other while the first is being cleaned out, thus preventing any stoppage. It is often found necessary to add lime to the water before pumping, on account of its having become acid, due to the decomposition of the pyrite in the sand. The lime can be conveniently added at the catch pits.

Costs.—The cost of sand filling varies considerably at different mines, but will, no doubt, be reduced as further economies are introduced.

COST OF SAND FILLING ON THE WITWATERSRAND

*It is interesting to note that the 103,261 tons of sand lowered at the Robinson Deep represents 98.1% of the total production of sand residue at this mine.

Some Tailing Dumps in the Peruvian Andes

By HOWLAND BANCROFT

A few months ago I went to Peru to examine several tailing dumps represented to contain an aggregate of 1,000,000 tons of tailing, and reported to average 8 oz. silver, 90c. gold, and about 70c. in mercury to the ton. Perhaps through ignorance on the part of the vendor's engineers, the tonnage was grossly overestimated. The topography of the country in which these dumps accumulated, together with the mode of deposition of these tailings, may serve in part as an excuse for the overestimation of the tonnage. Because of these facts, I submit the following brief description of the dumps, together with a few diagrams, as illustrations, with the hope that others having anything to do with similar dumps may be benefited.

Situation and Extent

The dumps under discussion lie at a general elevation of 14,000 ft. and are in scattered localities contiguous to railroad transportation in the central Peruvian Andes. Three different localities were examined, in each of which were two or more dumps. These dumps covered areas ranging from 20,000 sq. ft. to over 1,000,000 sq. ft., and varied in depth from a thin film of tailing less than an inch in thickness to small local accumulations having a maximum depth of 10 ft. In general, however, the dumps were exceedingly shallow, having an average depth of only a few inches. In the three localities examined, test pits were sunk, and estimates of tonnage made on 13 separate dumps. The result of the investigation disclosed the presence of 200,000 tons of tailing, instead of 1,000,000 tons as represented! And these were so scattered that the cost of collecting made the commercial treatment of the tailing impossible under existing conditions.

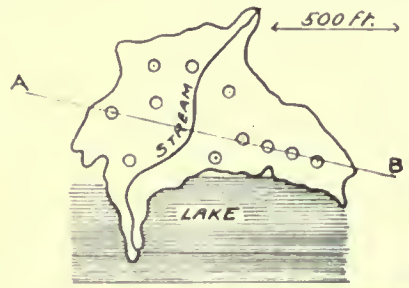

FIG. 1. PLAN OF TAILING DUMP, CENTRE OF CIRCLES MARKING TEST PIT.

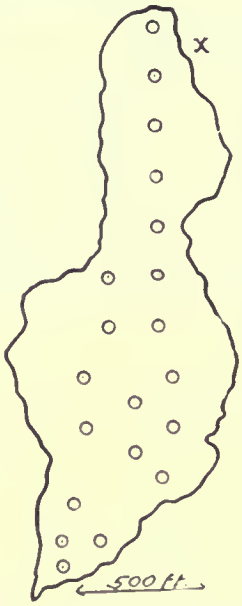

FIG. 3. PLAN OF TAILING DUMP SHOWN IN FIG. 4, CENTRE OF CIRCLES MARKING TEST PIT.

Relation of Topography to Dumps

East of the main range of the Peruvian Andes occur several smaller ranges separated by comparatively broad flat glacial valleys. Within the natural depressions in some of these valleys the tailings have accumulated. As the old mills were placed near a source of water supply and the drainage naturally followed the valley courses, the dumps in consequence have been formed where the streams or ditches debouched into flats. The surface of these dumps is extensive, and deceptive as regards the total amount of tailing to be expected beneath.

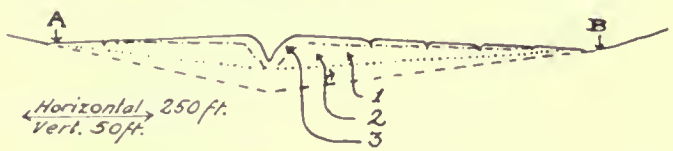

FIG. 2. GENERALIZED SECTION THROUGH DUMP. 1, ESTIMATED AS TAILING BY VENDOR; 2, DETAILED DEPOSITS, DRIFT, ETC.; 3, PROVED TAILING.

The small streams flowing through the valleys were

FIG. 4. PANORAMA OF TAILING DUMP, LOOKING SOUTH AND WEST. FOR OUTLINE SEE FIG. 3.; VIEW FROM POINT X. THE LAKE IN THE BACKGROUND APPEARS IN FIG. 1.

made to serve as power to turn the Chilean mills. The same streams carried off the tailing in suspension. Under normal conditions of stream flow, the major part of the tailing would be deposited where the stream or ditch emptied into a flat. However, when the streams overflowed the banks, due to floods caused by cloudbursts, or damming up of the outlets, or any other cause, the tailing was spread as a thin covering over a large area.

Estimation of Tonnage

The only excuse for the vendor's overestimation of the tonnage in the dumps examined is the partly excusable mistake of assuming that the courses of the streams now running through the tailing dumps were formed after the deposition of the tailing. Having this view in mind, the tailing was estimated, by the vendor, to be at least as deep as the bottom of the stream course, and to have an even slope along the bottom to the sides of the dumps.

As a matter of fact, there is every reason to believe that the present stream courses antedated the deposition of the tailing and that the streams were the chief agents in carrying and depositing the tailing. Consequently, these courses are lined by tailing, and wherever the gradient of the stream courses fell rapidly or the streams overflowed their banks, with a consequent decrease in the velocity of the current, the larger part of the load was dropped.

Attention is here called to Figures 1 to 5. Fig. 1 represents the outline of one of the dumps examined. Fig. 2 is a cross-section of this dump along the line A B shown in Fig. 1. It will be noted that the horizontal scale in Fig. 2 is 250 ft. to the inch, whereas in Fig. 1 it is 500 ft. Test pits were sunk in all the dumps examined. The position of these is shown by the circles, the pits being sunk at places represented by the centre of the circles. The test pits were, in general, 2 ft. wide, 4 ft. long, and varied in depth from 2 to 5 feet.

Reference to Fig. 2 will show that alluvium and silt cover the bedrock which forms the valley bottom. Through these the stream has cut to a depth of 10 ft. or more. As the banks of the stream are lined with tailing and the surface of the flat was covered with the same material, the vendor assumed that the tailing had an average depth of one-half the depth of the stream under all ground showing tailing on the surface. There is but little excuse for estimating tonnage in this manner. However, it was done.

When I examined these dumps their superficial nature attracted my attention from the first, and a few test pits served to prove conclusively that the deposits were, in general, very shallow. Fig. 2 illustrates in section the proved tailing and that part estimated as tailing by the vendor (which in reality is nothing but alluvium, silt, tundra, or similar material).

One can readily perceive how the vendor's estimate of 1,000,000 tons was cut down to 200,000! In conclusion, it is well to state that similar conditions may influence the deposition of tailing in localities other than those above described.

The New Zealand Government has introduced a bill in the House of Representatives to authorize the expenditure of £150,000, at a rate not exceeding £30,000 per annum, to provide bonuses for the production of iron and steel in the Dominion. The sum of 12s. ($2.88) per ton is payable for pig, puddled, bar iron, or steel from pig iron, and 24s. ($5.76) for steel direct from the blast-furnace, reducible after the first three years by 2s. (48c.) and 4s. (96c.) per ton, respectively, each succeeding year. The bill, if passed, will not come into operation until 1923, the intervening period being required for preparatory work in connection with the proposed new industry.

The Broken Hill South mine, working half time in September, produced 13,610 tons of ore, yielding 2431 tons of concentrate assaying 67.4% lead, 22.2 oz. silver, and 7.7% zinc.

Fig. 5. Part of a large open cut or *tajo*. The tailing resulted from crude milling of ore from this *tajo*.

SHOVEL MACHINE IN OPERATION AT FLAT RIVER LEAD MINES.

Shoveling Machines at Flat River

By E. H. LESLIE

Among the new devices that have been developed within the past few years to meet the requirements of increased tonnage operations, the shoveling machine has been offered to mine operators as an efficient substitute for the shoveler, and with a reduction in labor and mining costs. The shoveling machine has been given a thorough trial in the mines of the Flat River district, but while the figures presented in this article may be taken as fairly representative of the performance of this machine in the lead mines of Missouri, they can not be said to be completely representative. Conditions here are not ideal for the best results, in that its operation was not as continuous as could be hoped for to attain the highest possible efficiency.

The machine is not adapted to all classes of underground work, and economy through its use will depend upon its adaptability to the local conditions. Large stopes with an abundance of broken ore available at all times for shoveling afford the ideal condition for most efficient operation, as continuous operation and few changes in the position of the machine make for economy in its operation. Small stopes where only a few hours' work of shoveling can be provided and it is necessary to move the machine frequently from one stope to another in order to keep it supplied with ore, increase the operating cost and decrease the efficiency to that point where it is not possible to use it profitably.

The chief argument for the use of this shoveler in large mining operations is that it can be operated by one man and under favorable conditions will handle a large tonnage at a reduced cost. The machine will operate on either a smooth or rough floor, spading into the material and moving lumps which could only be moved by hand with difficulty. The conveyors on the machine may be used as picking tables when it is in operation. A full crew for operation consists of a runner with one man in front to clean up and two men behind to shift the cars. After the ore has been broken, the shoveling machine is run over the track to the stope and placed in position for work. The cars are moved into position by hand from the sidetrack and attached by a spring coupling to the loading machine in such a position as to receive the ore from the conveyor. As the cars are filled they are removed and empty cars brought into place, making possible an almost continuous operation.

Stability of the machine is obtained solely by its weight, no struts or anchors of any kind being used to hold it in position. When a narrow-gage track, of 24 in. for example, is used, as at Flat River, in order to enable the jib or shovel to swing laterally, it was found necessary to use outer rails at the loading faces and to place smooth-faced wheels on an extension of the axles to bear upon these rails, as will be seen in the halftone. This shoveler reaches 10 ft. to each side of the centre of the track, and can, therefore, clean up a space of 20 ft. from one position. The tracks are laid at distances which permit the machine to reach all of the broken ore.

This shoveler at Flat River is driven by a 22-hp., 60-cycle, 3-phase, 220-volt motor, and the reel which is seen mounted in the illustration carries 250 ft. of 3-conductor mining machine cable. The entire control is from a platform on the jib, one man controlling all of the movements of the apparatus. The vital part of the machine is, of course, the shovel and conveyor motions by which the material is picked up by the shovel and discharged on the conveyor, which is mounted on the jib, and delivered from that conveyor to the conveyor mounted on the main frame, which second conveyor delivers it into the mine cars.

In handling the disseminated lead ores of the Flat River district, the following figures present a record of its performance:

RECORD OF MYERS-WHALEY SHOVELING MACHINE

AT FEDERAL LEAD CO., SHAFT NO. 11

Tons shoveled 6962

Delays inherent in machine.	Hours.	*Miscellaneous delays.*	Hours.
Moving machine	10:48	Cleaning and repairing track	19:16
Off track	14:55	Blasting rock	35:30

Delays inherent in machine	99:30	18.56
Misc. delays (due to local conditions)	74:26	13.89
Net running time	362:04	67.55

LABOR REQUIRED TO OPERATE MACHINE FROM SEPTEMBER 3, TO OCTOBER 1, 1913

Average number of men per shift	4.3
Shifts	42
Runners	42
Sledgers	53
Car shifters	84
Scale of wages:	
Runner	$2.75
Sledgers	2.35
Car shifters	2.35

The repair charges of 0.033c. per ton at the St. Louis Smelting & Refining Co.'s property will appear high, but it must be said that the loader was operating at a shaft three-fourths of a mile from the machine-shop, and was charged with the time of the men going and coming as well as when actually working on the machine. The loader was new at the time of the test, and it was thought best not to have the operating men look after the repair work. The machine was carefully inspected at the end of each shift. The shovel used here is capable of handling 1000 lb. of material.

While sufficient data are not available at this time to state with any degree of accuracy just what the limits of economic performance are, there is reason to believe that the shoveling machine has found a place in the working of certain types of deposits, and a wider use will be found for it in the wholesale mining operations which are being conducted in this country.

Titus Chlorination Process

In his application for United States patent No. 1,111,976, the inventor, Court C. Titus, of Helena, Montana, describes his chlorination process as follows: According to the preferred process, the ore is crushed to about 20 mesh, dried by heating in a rotary drum, and then delivered into one end of a long narrow inclined revolving cylinder. A mixture of dry chlorine gas and air is introduced into the other end of this cylinder, converting the iron into its oxide, and the other metals and the metalloids into their chlorides. The metalloid chlorides, such as those of sulphur, arsenic, or antimony, are volatilized and are either allowed to escape from the upper end of the cylinder, or are collected and condensed. The treatment with chlorine and air is continued for several hours, the ore meanwhile gradually moving downward through the cylinder and discharging from its lower end. While the reactions evolve considerable heat, it is as well to apply heat to the lower end of the cylinder, and finally to raise the ore to as high a temperature as possible without causing it to fuse partly and agglomerate, say to 240 to 250°C. The ore may then be treated in any appropriate manner to recover the metals.

GOLD OUTPUT of Rhodesia in September was worth £309,398, making a total of £2,621,586 for the nine months of 1914. The Cam & Motor produced £16,709 from 11,870 tons. In August the Shamva treated 47,718 tons for £31,283. Ore reserves of the Globe & Phoenix were estimated as 188,000 tons averaging $29.10 per ton on September 30.

THE MT. LYELL MINE, Tasmania, produced 641 tons of blister copper, 36,353 oz. silver, and 846 oz. gold, from 25,204 tons of ore, in September. Two blast-furnaces worked 28 and one 21 days.

GRAVEL WASHED by the Lena Goldfields company, Siberia, from October 1, 1913, to August 31, 1914, totaled 756,413 cu. yd., yielding 326,802 oz. gold.

Steel Roll Shells

By JAMES C. H. FERGUSON

*The importance of having roll shells which wear even, and have a good life, is recognized by millmen, who know that the use of such shells results in efficient crushing and economy.

Without going into an elaborate history of the subject, the following may be mentioned treating on the evolution of roll shells. During the early days of mining machinery construction, cast iron was used for practically all such grinding devices as those under consideration, usually some good mixture of gray iron being the most suitable for wearing qualities. Sometimes, though not often, shells or muller rings, chilled to a depth of from ½ to 1 in. through the face, were used. But it soon became apparent that cast iron, no matter how well selected as to grade or mixture, or how carefully molded or chilled as to physical appearance, was not a suitable material to use for grinding rings or dies, since, for the proper performance of their work, absolute homogeneity and freedom from blow-holes or other imperfections are highly important. Steel, that is, cast steel, therefore, was next and most logically considered as being more suitable to fulfill the *desiderata* just mentioned. Although it was more expensive than cast iron, it was harder and tougher, and of infinitely better wearing quality. But even cast steel failed to give satisfaction, particularly on the high-speed rolls of narrow face and large diameters designed by the leading manufacturers during the past two decades. It was for that reason that the steelmaker soon recognized the importance of meeting the situation and has during the period mentioned evolved the rolled-steel roll shell. This was a natural evolution, and during the past 10 years practically no other material has been used except for some small or slow-running mills where the expense of steel shells was not warranted. While, as mentioned above, the application of steel shells as wearing parts in the various types of grinding mills was comparatively new, the purely mechanical features of their manufacture were easily accomplished by the use of tire-rolling mills, which for many years previous had been used for making locomotive driving-wheel and car-wheel tires.

Chemical and physical properties of the best roll shells of American manufacture are as follows:

Chemical properties.	Per cent.
Carbon	0.65 to 0.80
Phosphorus, not to exceed	0.05
Sulphur, not to exceed	0.04
Manganese	0.60 to 0.85
Silicon	0.15 to 0.30

The above are the average ranges used. Shells which have given good satisfaction in actual operation had the following analyses in the heats from which they were produced:

	Per cent.	Per cent.	Per cent.
Carbon	0.700	0.730	0.780
Phosphorus	0.035	0.029	0.015
Sulphur	0.022	0.018	0.028
Manganese	0.741	0.786	0.745
Silicon	0.253	0.252	0.258

These results show that the shells are very uniform in composition.

Physical properties.	
Tensile strength, pounds	125,000
Elastic limit, pounds	72,000
Extension, per cent	10
Contraction of area, per cent	15

The following gives the limits of sizes for rolling as used in the practice of one of the largest tire manufacturers in the United States: roll shells 8 to 10 in. wide, 108 in. outside diameter by 3 in. thick; over 10 to 16 in., or under, 68 in., outside diameter by 3 in. thick.

Shells over 16 in. wide and thicker than 5 in. and weighing say 5000 lb., or over, are produced to the best advantage under a hydraulic forging press of adequate power, as a strictly forged, instead of a rolled product. Sufficient stress cannot be laid upon the necessity of thoroughly working the metal in these forgings all the way to the centre by the use of machinery of this kind, which is sufficiently heavy and powerful to perform the necessary forging operation and is better able to do so than rolls. I am quite convinced that most of the cases of uneven wear in roll shells of extreme widths, where not due to improper setting or improper mill feeding, or both, is largely owing to the fact that the metal is not of uniform density, resulting from being worked in a tire mill, which was too light for the heavy and thick section passing through the rolls.

As regards the life of shells, reports from users in Montana, Colorado, Sonora, Arizona, and Utah show interesting results. In one instance the amount of rock crushed per pound of steel consumed was 1.06 tons, and in another 4.25 and 3.8 tons. When new, a set of three shells weighed 4464 lb., and on discarding, 1640 pounds.

*Abstract from *Transactions* of A. I. M. E., Pittsburgh meeting, October 1914.

Mexican Ports of Entry

The amount of imports passing through the various gates of Mexico during the last two normal years were as follows:

	1910-11	1911-12
Gulf ports	₱134,128,467	₱125,654,614
Pacific ports	11,667,537	11,362,240
Northern frontier ports	59,956,902	45,602,016
Southern frontier ports	121,365	43,439
Total	₱205,874,271	₱182,662,309

Of the total imports 79.79% were subject to duty, and 20.21% entered free of duty. It is therefore of importance to the manufacturer to investigate the subject of duties thoroughly if making prices for delivery in Mexico, as in some classes of material this often amounts to from 50 to 75% of the value of the product.

Petroleum in India

*It is announced that during the coming year the Geological Survey of India will make special inquiries into the petroleum resources of the Punjab, Northwest frontier province, and Baluchistan. The petroleum beds of these parts have never been examined minutely, but a good deal is known about them.

The records of the Survey show that the petroleum resources of India are confined to the two systems of folded rocks at either end of the Himalayas, namely: (1) the Iranian system on the west, including the Punjab and Baluchistan and continuing beyond British limits to Persia, and (2) the Arakan system on the east, including Assam and Burma, with their southern geotectonic extension to the highly productive oilfields of Sumatra, Java, and Borneo. In both areas the oil is associated with Tertiary strata, but there, so far as present knowledge goes, the similarity between the two oilfields ends. The great resources of the Burma wells, and of the Assam oilfields behind them, are well known: but the superficial knowledge already available regarding supplies in the northwest, points to the conclusion that what may be found there will hardly compare favorably with the supplies farther east.

The petroleum occurs in loose-textured conglomerates and sandstones, its distribution, which is similar to that of water in porous strata, being controlled as in the Burma area, by impervious beds of clay. It may exude through any accidental fissure at the surface of the earth and thus form natural oil springs, but is chiefly obtained by boring through the impervious covering strata into the oil sands below, from which the oil may be raised by pumping.

The great difference between the oilfields of Burma and those of the northwest, appears to be that, whereas in Burma the conditions for the retention of the oil have been ideal, in the northwest they are not.

*Abstract from *Daily Consular Report*.

Quartz Mining in Dutch Guiana

While attention has heretofore been directed mainly to placer mining, gold-bearing quartz veins are known to occur in Surinam and several attempts have been made to open them. The best known workings are those of the Guiana Gold Placer concession, a Dutch concern, holding claims along Mindrenettie creek, a tributary of Saramacca river, about 120 kilometres from the coast. The region is heavily wooded and low lying. Quartz veins have been reported at a number of points. Near the corner of the De Jong placer, one known as the 'Koolhoven riff' attracted the attention of the Guiana Calloa Gold M. Co., a New York concern, and serious efforts were made to develop it, but without satisfactory results. As early as 1903, attempts were made by the Dutch company to work one of the veins, and a 40 stamp mill was imported from the United States and erected. At the site chosen the quantity of ore proved inadequate. Whether better results would follow more adequate prospecting is not certain, since little definite information about the veins is available, though H. J. Verloop has studied the geology. A railroad traverses the area and much more inaccessible territories have been far more adequately prospected.

RAILROAD THROUGH GUIANA GOLD PLACER CO.'S CONCESSION.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this depar'ment for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Rand Banket

Reply by Mr. Horwood to J. W. Gregory's Discussion, Dated Glasgow, May 5, 1914 (Continued)

Gregory now maintains that the pseudomorphic nature of the pyrite does not support the infiltration theory, as it does not prove whence the pyrite came. It proves at least that metasomatic processes have occurred similar to those with which one is acquainted in ordinary gold-quartz veins. It also suggests strongly the action of deep seated circulating solutions, as I showed that the evidence pointed to the change having taken place under high temperature conditions.

As regards the carbon, it does also occur, occasionally, without pebbles, in the quartzite, in which case the latter carries gold. I admitted that small proportions of gold, pyrite, and metals of the platinum group may occur that are of detrital origin. I particularly pointed out that the iridosmine from the Rand banket differed in its microscopical characters from that of known detrital origin. In addition to its association with gold, silver, pyrite, carbon, traces of cobalt, and also with chromium, all of which occur in the neighboring dikes, I adduced several further facts and arguments that suggested the dikes as the responsible agents for these rare metals.

Gregory says I have graphically described the main facts in the Rand goldfield and claims that I showed how different it is from any lode-mining field. My description may have indicated how, on first impression or to a casual observer, the banket does seem to differ from ordinary lode deposits, and how it certainly does in appearance; yet, I also tried to make it quite clear that it is in no wise really different in essentials.

Gregory speaks of the poverty in gold when the pebbles are angular. I particularly pointed out that pyrite pseudomorphs are invariably associated with good ore, and I stated that some of these pseudomorphs were formed by the replacement of angular, indurated, slaty-quartzite pebbles, and have retained the original angular outlines, and I called attention to the frequency of this particular form of pyrite replacement.

I defined my terms, taking them from well-known authorities, when dealing with the question of the occurrence of ore-shoots, and showed that they certainly do occur on the Rand, and are particularly in evidence in the Nigel mine. Gregory weakens his argument by inventing for a shoot a definition of his own. He now says that he has examined the best known of these occurrences and shown that it was not a shoot of gold in a widespread sheet of material like a shoot in a quartz lode, but a single band of conglomerate in an old channel and the ore was bounded on each side by quartzite. As he gives no further particulars, I assume that the occurrence that he calls the best known is the one in the May Consolidated mine, mentioned in his paper. He refers to it in the following words: "Ross Browne has kindly given me an account of a band of quartzite in the May Consolidated mine, which had been deposited in a 'wash-out' cut through the banket. The conglomerate had been deposited as a sheet of shingle, through which a channel had been cut and filled with sand. Some patches of the shingle remained undenuded, and thus blocks of conglomerate rich in gold have been left in the barren channel of quartzite. According to Mr. Browne, and the evidence certainly appears to support his conclusion, the gold must have been introduced into the conglomerate before the erosion of the channel; and the gold must have been deposited contemporaneously with the formation of the conglomerate, and not by any long subsequent process of infiltration." Professor Gregory adds a footnote that this case appears to establish conclusively that the gold was deposited simultaneously with the beds. After such a definite statement, followed by such a sweeping conclusion, one is therefore not a little surprised to find that Ross E. Browne contributed to the discussion on Gregory's paper in the following words: "Professor Gregory, in his very interesting paper, refers to certain information obtained from me in a way that calls for some explanation. The channel mentioned as occurring in the May Consolidated mine was pointed out to me by the consulting engineer, George Hoffmann. We followed the development from level to level and concluded that the well marked course was most probably that of an eroded channel, but, in the absence of cross-cuts or continuous drives to follow the rims and expose the bottom, the evidence was not conclusive. It was stated that in the drives crossing the supposed channel through barren quartzite there were encountered several isolated patches or fragments of gold-bearing banket. To verify and complete the information, there would have been required a very considerable amount of work, and owing to the press of business the matter was dropped."

Gregory says that the distribution of the rich and poor material illustrated by my figures No. 25 and 26 correspond better with the patchy distribution of gold in a placer deposit than with shoots in a lode. These two diagrams, and the two accompanying curves, I had compiled from two mines that were under my

technical control, and I can vouch for their accuracy. There is no such regular alternation of relatively rich and poor ground between two layers separated by varying distances of from 50 to 200 ft. of quartzite in a placer deposit. Also against Gregory's statement is that of no less an authority than Waldemar Lindgren, who in his discussion on my paper dated April 16, from Boston, Massachusetts, writes in reference to these same diagrams and those accompanying them: "Most important are also the statements and diagrams referring to the distribution of the gold in the various conglomerates; these sections are perhaps the most convincing arguments brought forward to support the infiltration theory."

Gregory then deals with nine features to which, *among others,* I drew attention as militating against a placer theory and that may, on the other hand, be regarded as evidence that the auriferous banket is merely an abnormal type of lode deposit.

As regards his criticisms on the first, namely, the great depth to which the profitable ore extends, these are already answered in my reply to T. A. Rickard's discussion.

As regards his remarks on the second, the dryness of mines in depth, I do not know whether he really intends them to be taken seriously. The dryness of mines in depth surely demonstrates that the circulation of the ground-water does not usually account for the formation of veins. Particularly is this so in the case of the Rand, where miles of adjacent deep-level mines communicate with the surface through the old workings of the outcrop mines, and therefore are well placed to act as huge drains to an enormous catchment area; and yet the deep levels are characterized by being dry and dusty. As to the third, the abundant water-ways by which mineralizers could have ascended, Gregory says he is without evidence of such channels, although I pointed out that the gold of the banket is genetically connected with main structural faults and with basic dike intrusions that mark fissure-faults, and that the bankets acted in place of ready made fissures; and Malcolm Maclaren had clearly shown, when he discussed Gregory's paper, that the bankets are more porous than the sandstones. Gregory could hardly have made such a statement had he, during his brief visit to the Rand, spent as much time as possible actually underground in the mines, observing and recording facts for himself.

As regards the influence of dikes, the following is a quotation from a letter to me from Johannesburg, from David Wilkinson: "You are also probably aware that some of our richest specimens have been found associated with dikes, sometimes in quartz veins that occur in fissures in the dikes, and at the Witwatersrand Deep we have often found considerable occurrences of galena and some zinc ore in these quartz veins." He then refers to a specimen rich in gold that occurred in a dike in the Witwatersrand Deep mine, and then continues: "You probably remember the wonderful specimen from the Rose Deep, which was found close to the longitudinal dike that divides the property. Obviously, this is not alluvial gold." S. H. Cox, in discussing Gregory's paper, stated that the fact that the proximity of dikes does not always exercise any influence on the grade of the ore did not affect the question; and that in every case with which he was acquainted where dikes have penetrated rocks that have been subsequently charged by infiltrating solutions there are points of contact where no mineralization occurs, and the ascending solutions have not always passed through well marked channels, but frequently through shattered rocks. Gregory, while admitting the abnormal richness of the banket, does not understand the rôle played by the dikes, because he takes too small, or circumscribed, a view of the occurrence and does not realize that there is no occasion to expect that the ore will in every case be enriched or impoverished at or near the immediate contacts with the dikes. Speaking of the Rand as a whole, one of the outstanding features is that it is traversed by numerous longitudinal diabase dikes. All the gold occurs in their neighborhood and they are exposed in the underground workings of practically every mine on the Rand.

Gregory, after remarking that one of the most important features of my paper is the series of photographs showing the microscopic structure of the banket, states that they reveal its microscopic characteristics to be quite unlike those of any known lode. This surely is only what one would expect as the outstanding physical features of the banket are so different from those of normal lodes. He argues that lodes due to infiltration usually show a gradual passage from the country-rock through a silicified stage into sheets of vein-quartz, unless they have been deposited in fissures; whereas he thinks that in the banket many of the richest samples have been no more altered than barren samples. In the case of these deposits I pointed out that the bankets themselves have served in lieu of fissures. I dealt at considerable length in my paper, when discussing the question of local indications of good ore, with the alterations undergone by the richer portions of the banket; and showed that in consequence of its altered physical character mine managers and mine foremen can readily tell from its appearance whether it is rich or poor. In this connection I would like to mention the following details of an occurrence in the Consolidated Main Reef mine as given to me by David Wilkinson. "Usually, there is above the South Reef Leader a 'bastard' leader of from 4 to 8 inches in width, and sometimes there are two or three of these, but usually only one. I estimated some years ago that I have taken between 500 to 600 samples of this 'bastard,' and usually obtained about a pennyweight in value, and never, with the two exceptions I am now going to give you, as high as 2 dwt. On the 5th East from the old West shaft, the drive encounters a dike which has a southeast bearing. About 12 ft. from this dike, the bastard reef contained a large percentage of silica, so much in fact that the small pebbles in the bastard reef were almost obliterated. I may

say that the South Reef Leader at this place was very rich. I took two samples from the bastard reef, one at 10 ft. from the dike and the other at 5 ft., and was greatly astonished to find that they assayed about 35 dwt. I was so surprised at this result that I went down the mine specially and took two special samples from this bastard reef. I brought them to the surface, had them carefully crushed under my supervision, and found that my original assays were approximately correct. Now you will see that this gold at any rate did not occur originally in the bastard reef, otherwise you must explain how over a length of about 1300 ft. and a number of levels no gold of more than about a pennyweight was found. At the time I took these samples, I regarded this occurrence as an absolute proof of the infiltration of the gold into this bastard reef."

Gregory maintains that since the matrix of the banket consists mainly of grains of silica, it would, if the gold were due to infiltration, have been readily altered into vein-quartz, whereas he supposes that the matrix of even the richest Rand ore is often practically unaltered. Now the matrix of the banket has been greatly altered, for it has been silicified by the abundant deposition of secondary silica; from his argument one is bound to assume that Gregory imagines nature would be so wasteful of her energies as to replace with fresh silica the grains of silica already existing. In this connection, I cannot do better than quote verbatim from Maclaren's criticism of Gregory's paper: "Professor Gregory affirmed that there was no evidence of infiltration in the banket-matrix; but what of the secondary silica? Was not that a mineral of infiltration? And the pyrite, to which such an important rôle had been assigned—was not that a mineral of infiltration? As evidence against infiltration it had been objected that the banket-matrix had not been replaced by vein-quartz. But nature wasted no energy, and finding quartz (as grains) already in position was content to fill up, in obedience to the ordinary laws of mass action, the interstices between those grains; the silica deposited tending to arrange its molecules in consonance with the crystallographic axes of the grain upon which it was deposited. Than that, further silicious deposition was impossible, since in infiltration like did not replace like; like merely added itself to like." As further evidence of the alteration it has undergone and of its resemblance to ordinary lodes, I dwelt at length in my paper on the metasomatism that had taken place in the banket, pyrite having replaced quartz and quartzite, the original structure in some cases having been preserved so as to be distinctly discernible by the aid of the microscope.

The fourth argument, namely, the crystalline character of the gold, Gregory attempts to brush aside by maintaining that "it is part of the placer theory, according to which the gold has been re-dissolved and redeposited during the cementing of the banket." The fact that no nuggets are found and that the gold is usually not discernible to the naked eye and that in exceptional cases when it is visible it is crystalline and shows no sign of being water-worn[1] is usually accepted as strong evidence against an alluvial origin. I shall here quote one of the reasons that D. Wilkinson gave me for his belief in the infiltration theory. When he first came to the Rand, he spent nearly three years in the various capacities of sampler, assayer, and surveyor at the Consolidated Main Reef mine. He told me that he estimated that during that period he took about 8000 samples, which he assayed himself, and that he never saw even a speck of gold in any of these samples. Further, he took elaborate measures to determine the probable occurrence of 'metallics' on a 60-mesh screen, and never found a single particle. As he remarked, his experience as a sampler is in accord with that of other samplers on the Rand, except that in some few mines occasionally visible gold is found; however, in such cases, it is, as far as he is aware, always more or less crystalline in form. Doubtless Gregory would try to explain this by saying that the original alluvial gold had been dissolved and re-distributed in a very fine state of division. However, it is difficult to imagine that such a process over such an extensive area and on such a large scale would have taken place so completely as to have left no trace of any of the original placer-gold. As was pointed out in the discussion on Gregory's paper, in order to explain how such reactions occurred one has to imagine the former presence of conditions and material that were highly improbable, and he has not produced any evidence of such. Further, why attempt to explain the origin of the gold by such a complicated double process, when the well known ones that have taken place in the formation of ordinary gold-quartz veins are amply sufficient to account for the gold in the banket, and the evidence points clearly to them being also in this case the responsible agents?

In dealing with the occasional association of the gold with veins of quartz, Gregory remarks that the latter have no bearing on the main question, as they are secondary products of the same period, and are only of historic interest. As this is merely a dogmatic statement of personal opinion, based on a few weeks' visit to the Rand, and is not supported by any scientific evidence, it calls for no refutation.

The close association of the gold and pyrite—which forms the sixth argument—he maintains is not constant, some rich ore being poor in pyrite, and some poor ore very rich in it. I particularly stated that "other things being equal, the presence of more than a usual amount of iron pyrite in the banket is usually, though not invariably, an indication of good ore." In my treatise I demonstrated the metasomatic origin of the pyrite 'pebbles,' and pointed out that the latter were a sure indication of good ore, and that this fact and also the frequent close and intimate intergrowth of the gold and pyrite formed sufficient evidence that the gold and

[1]The grains of gold are often of very irregular shape with hackly surfaces and jagged outlines.

pyrite had been deposited from the same solutions, often simultaneously. I mentioned that De Launay had stated that while the gold in the banket is constantly associated with pyrite it does not seem to be combined with it and can often be seen, by the aid of a microscope, in crystals enclosed within the pyrite. I showed that the gold present in the pyrite of the Rand banket is mainly bound up in it mechanically, as is clear from the following facts, namely, that in panning, when crushed fine, it is easily detected and separated (or most of it) from the pyrite: from microscopical investigations: from its largely yielding to amalgamation; and from the battery-pulp readily giving up its gold in the cyanide process.[5]

As regards the seventh argument, that the occasional presence of calcite, tourmaline, galena, blende, copper pyrite, pyrrhotite, iridosmine, and other metals of the platinum group supports the infiltration theory, he contends that their presence is fully consistent with the placer theory as, according to him, most of them must have been present as detritus in the pebble beds, and the presence of platinum and iridosmine is thus more easily explained. Were Gregory personally familiar with the way in which the first six occur in the mines, often in conjunction with vein-quartz or occupying vugs, I think his belief in his placer theory would receive a rude shock, for the occurrences are not those of water-worn fragments; they are intimately associated with the gold and pyrite, and are so very similar to the occasional occurrences of such materials that one sees in ordinary lodes.[6] He would, doubtless, summon to his aid the second, or re-solution, portion of his hybrid theory, and say that originally these materials occurred as water-worn débris, and had since been dissolved and re-precipitated. As already mentioned, the improbability of such complicated processes was clearly and ably shown in the discussion on his paper, and as he brought forward no supporting evidence, it seems quite unnecessary to make further comment here. As regards the presence of iridosmine and other metals of the platinum group, while admitting in my paper that there may be a small proportion that is of detrital origin, I stated that the facts and arguments I gave together with its association with gold, silver, pyrite, carbon, traces of cobalt, and with chromium, all of which I had showed occur in the neighboring dikes, indicated the latter as the main source of the minute quantities of these rare metals in the auriferous banket.

Gregory then refers to the distribution of the gold and says: "Its limitation in paying quantities to the beds of water-worn banket, and its absence from the beds of equally permeable 'bastard' reef above and below the rich seams, are facts also consistent with its detrital origin." He then says that my arguments for the infiltration theory appear to be not only consistent with the placer theory, but to tell in its favor. These again are expressions of personal opinion, instead of scientific evidence. In the discussion on Gregory's paper it was conclusively shown that the "bastard reefs" are less porous than the banket proper. I have just given an instance of a normally barren "bastard reef," assaying where greatly silicified near a dike about 35 dwt. of fine gold per ton.

Among some of the facts adduced by me as evidence that these deposits are merely an abnormal type of lode occurrence was the influence exercised by slate and shale on the mineral deposition. Gregory carefully ignored this feature. I explained why certain banket beds had been selected and how the presence of slate and shale had influenced this selection. In his paper he stated that "the most striking feature in the vertical distribution of the gold is its limitation to a seam of conglomerate, which may be only a few inches thick, while the beds above and below are practically barren." However, he is not altogether correct in speaking of its limitation in profitable amounts to the banket. For example, gold occurs in places, in profitable quantity in the pyritic quartzites known as the 'pyritic band.' Although I have already given Mr. Wilkinson's description of one such occurrence, I shall refer to it again here in his own words: "Many years ago, I examined these quartzites very carefully at the Wolhuter, and I found that, while very often the pyrite occurred in layers parallel to the bedding, in many other cases it occurs irregularly across the bedding. This pyrite, to my mind, is undoubtedly due to an infiltration. It cannot possibly be due to the sedimentation of pyrite because of its form, and as you know some of this pyritic quartzite yields from 10 to 15 dwt. of gold in places."

I think I have now dealt with all the main points in professor Gregory's criticism.

C. Baring Horwood.

London, September 22.

[5]An interesting feature that I had not mentioned, showing how intimately the Rand gold is bound up with the pyrite, is that the 5% of pyrite in the sand, after the classification of the pulp leaving the stamp-batteries, contains 70% of all the gold in the sand (*The Mining Magazine*, Oct. 1912, p. 250).

[6]Always allowing, of course, for the difference in the appearance of the lode-filling, due to the presence of the conglomerate pebbles that occupy most of the space between the walls.

Gold output of West Africa in September was 37,525 oz., against 36,611 oz. in August. Returns from the principal mines are as follows:

	Tons.	Value.
Abbontiakoon	11,147	£23,705
Abosso	9,138	16,493
Akoko	140	144
Ashanti	9,149	38,184
Broomassie	4,244	13,653
Cinnamon Bippo	2,278	4,016
Prestea Block A	23,274	37,784
Taquah	5,600	16,544

Men employed at Broken Hill, New South Wales, at the end of June totaled 8932, and at the end of September, 5305. There are also 1067 working on the new water scheme and railroad. Wages are now £10,000 to £12,000 per week, against £30,000 to £33,000 before the war.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PRUSSIAN BLUE, $Fe_4(FeCN_6)_3$, is sometimes used to color tea leaves.

CARGO WEIGHING 583,949 tons has passed through the Panama canal in the period of August 15 to October 15.

THE SLIDE which blocked the Culebra cut at Panama, on October 15, contained about 720,000 cu. yd. of earth and rock, of equal portions. Five dredges moved 119,605 yd. in 6 days, making a temporary channel for vessels to pass through.

COST of working a 900-hp. Diesel engine at the Anheuser-Busch brewery, St. Louis, totals 0.6506c. per kilowatt-hour as follows: fuel oil, 0.2850c.; lubricating oil, 0.0263c.; water, 0.0388c.; supplies, 0.0043c.; labor, 0.2750c.; and maintenance and repairs, 0.0212 cents.

KAURI GUM, a resin mined in New Zealand, is mostly used in making varnish. In cleaning the material for export, a good deal of 'chips' and 'dust' is made, and which formerly found no market. Recently Germany has taken this refuse and uses it in the manufacture of linoleum.

CAGES in numbers of shafts at Kalgoorlie have gates fitted to them to prevent men falling out during hoisting. No accidents have resulted from their successful use. Fixed chairs, for the cages to rest on at levels, have caused a good many accidents, and they have been dispensed with in favor of traveling chairs attached to the cages.

CALCULATION of wind stresses, and design of framework in tall buildings to afford the most rigid and economical resistance to them, are of great importance. Such pressures are affected by altitude, temperature changes, suction on the leeward side of the building, and gusts. The period of vibration of a high building is from 2 to 4 seconds.

AN EXCELLENT LUBRICANT for use with burette stopcocks, desiccators, etc., can be made by melting together equal parts of paraffin and vaseline, according to E. W. Osgerby, in *The Journal of Industrial and Engineering Chemistry*. The paraffin gives body to the mixture which is therefore superior to vaseline alone, especially in places where high temperatures prevail.

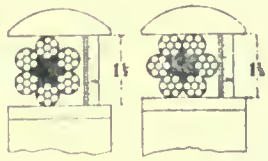
MEN EMPLOYED in gold mining and treatment in Western Australia in 1913 totaled 13,445, producing 393.36 tons per man underground, and 214.08 tons for miners and millmen. This ore contained 181.50 and 98.78 oz. respectively. There were 767 accidents in all metal and coal mines, of which 26 were fatal, equal to 1.76 per 1000 employed (14,780).

THE MINERAL RESOURCES of Morocco, Northwest Africa, are as yet but imperfectly known. Copper, silver, gold, and iron ores exist in the Sus provinces. An international arbitral commission has been sitting in Paris to settle the various denouncements filed by prospecting syndicates prior to the recent promulgation of the mining code for Morocco.

BAGASSE is the term given to the residue of cane after the sugar has been extracted. It has little value as a fertilizer, is sometimes fed to stock, but is a fairly good fuel, as it averages over 8000 B.t.u., against 13,000 B.t.u. for anthracite coal. In sugar mills it is often used under steam boilers. In Queensland this is done everywhere. The clinker produced during combustion is like a highly mineralized rock.

CONFUSION of the terms 'cyanide' and 'cyanite' are sometimes the cause of mistakes by laymen. The former is used in gold extraction and has the formula KCN or NaCN, while the latter is a bluish silicate of alumina, with the formula $Al_2O_3 \cdot SiO_2$. At the start of the war in Europe it was feared that there would be a shortage of cyanide for Western Australia, and it was seriously published in some papers that a deposit of cyanide had been found in New Caledonia!

THE TRUE DIAMETER of a wire rope is expressed by the diameter of a circle which will enclose it. Therefore, in using a caliper rule, be careful to avoid measuring across two strands side by side; measure rather from the top of any one strand to the top of the strand directly opposite, according to A. Leschen & Sons Rope Co., of St. Louis. This is most important, as otherwise the rope ordered is likely to be too small.



IRON is not made in New Zealand, although there are large deposits of ore at Paparoa, and immense quantities of iron sand on the west coast of the North Island. The latter contains 8 to 9.2% titanium. As the result of successful experiments in its treatment by the Waihi Gold Mining Co., it is proposed to erect a small blast-furnace near New Plymouth, not far from the iron sand beaches. The process is to briquette 60% of sand with 40% small coal from the Liverpool state colliery. The briquettes will be coked before being fed to the furnace.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

THE PORPHYRY COMPANIES IN THE THIRD QUARTER OF 1914.—LABOR AT BUTTE, AND THE ANACONDA COMPANY'S OPERATIONS.—FOREIGN LABOR IN ARIZONA MINES.—OHIO COPPER COMPANY.

The quarterly reports of the principal copper mining companies for the third quarter of the year are appearing, and do not reflect as serious an increase of cost, due to the lessened output, as might have been expected. The Miami reports that although it is producing at half its normal capacity, it has made a slight decrease in operating costs. The recovery in milling now averages between 70 and 74%, and reduction in underground costs has been made, the two together leading to a production cost per pound of copper that is nearly as low as the Company has ever made at any time. The No. 6 unit of the mill is reported as recovering 2 lb. copper per ton more than the other units, and it is said that when the mill is operating at full capacity all will do better work than before. Details of the Ray and Chino reports appear in the news section of this issue.

It will be interesting to see what the effect is of the order of the Governor of Montana suspending martial law and withdrawing the state troops from Butte. Probably matters will remain quiet, for it is scarcely possible that the miners are so ignorant of the present situation that they would attempt to make difficulties at a time when every other consideration points toward the advisability of the Anaconda shutting down completely. It certainly cannot be making much money operating at half capacity at the present price of copper, and if shipments to Europe continue to be interfered with, the Anaconda management might decide that the best thing to relieve the situation would be for it to close and remove its own considerable production from the monthly output, instead of attempting to bring about a further reduction on the part of all the other companies. The transfer of the assets of the International Smelting & Refining Co. to the Anaconda has been almost completely carried out, and all the stock has been turned in on the basis of 3.3 shares of Anaconda for one of International, except a little over 100 shares. Good progress is being made with the construction of the new smelter at Miami, but naturally the work is not being pushed very fast, since the operations of the Inspiration which will be the principal source of ore, are being held back until the copper situation clears.

For some time a certain political element in Arizona has been trying to bring about the passage of a law to prevent the employment of Mexicans in Arizona, although the law is so framed as to include all foreigners, in order not to appear as a direct discrimination against the many Mexicans who come over the border to get employment in Arizona and New Mexico. A law recently passed provides that 80% of employees of mining companies shall be citizens of the state. As about two-thirds of the men now employed in mines and mills are not citizens of the United States, this law, if held constitutional, will cause a considerable change in the labor situation. The climate of Arizona is such that it does not appeal to those accustomed to a more northern latitude, and the Mexicans who are used to such conditions are the easiest to secure. There is some probability that the law will not be sustained by the courts, but even if it is, it may not work out so much to the disadvantage of the mining companies as is being anticipated. If workmen had to be brought into Arizona from other parts of the United States, care would be taken to get the best class of men available, and though they would doubtless demand higher wages, it is quite probable that their greater efficiency would serve to make up the difference.

The control of the Ohio Copper Mining Co. has been taken over by Clark Grove, representing the Mine & Smelter Supply Co., E. McCormick of the Railway Steel Spring Co., and Charles T. Lark, the Heinze interests, the three men representing the creditors. It is reported that the whole staff appointed earlier in the year, when the control of the Company passed to the Allison interests, has been dismissed.

The copper market was fairly firm throughout last week, and scored a marked advance, ½c. per pound, at the close when domestic consumers began to place considerable orders. Shipments to England and France continue in good volume, but no figures are available. It seems not improbable that some satisfactory arrangement can be reached in regard to shipments to other European countries, as Denmark, Norway, and Sweden have already given such sweeping guarantees that Great Britain has announced that it will not interfere with shipments to those countries.

HOUGHTON, MICHIGAN

PROTEST SENT REGARDING COPPER SEIZURES.—TAXES.—COPPER SHIPMENTS.—TAMARACK REGRINDING PLANT.

The Copper Country Commercial Club has sent a telegram to the Secretary of State protesting against the action of Great Britain in detaining vessels bearing copper from the United States to neutral foreign countries and the putting of unwrought copper on the list of absolute contraband. The protest calls attention to the fact that the Michigan copper district produces 230,000,000 lb. of copper annually, of which more than 60% is exported.

Several weeks ago a petition was sent to the State Tax Commission requesting a review of the Houghton County assessments. The Commission replied that because of scheduled duties, it would not be able to comply with this request until December 1. According to state law, the supervisors must have their tax rolls completed and in the hands of the treasurers on December 1. On that date the treasurers begin collecting the tax, and until January 10 a 1% commission or collection fee is added to the tax. From January 10 to March 1 a fee of 4% is added to the tax. Since it requires about a month for the supervisor to prepare the tax roll for the treasurer, and if the Tax Commission review should last for any length of time, it is evident that the treasurers will not receive the tax rolls until after the period during which the 1% commission is added. The interesting question then arises as to whether the taxpayers of Houghton county will have to pay the 4% collection fee after January 10 as provided by law, if the payment of these taxes is held up by the State Tax Commission.

Recently a cargo record was made at the Presque Isle harbor of the Marquette iron range. During the past week the largest shipment of refined copper ever made from the Michigan district was taken to Buffalo by the Mutual Transit Co.'s steamer *North Star*. The cargo totaled 9,000,000 lb. and in-

cluded consignments from the Calumet & Hecla dock on Torch lake, the smelter dock at Dollar bay, and the Quincy and Copper Range docks on Portage lake.

Construction of the railroad spur to the new regrinding plant of the Tamarack Mining Co. at Hubbell is now under way. Three cars of steel have been delivered at the mill, and 15 men of the American Bridge Co. are now placing the steel in position. Work on this new plant has continued in spite of the general curtailment, and its erection is being rushed as much as possible.

The Osceola mine is producing about 4200 tons of ore per day from five shafts. In October the output of copper was 1,100,000 lb.——A large reservoir is being constructed by the Calumet & Hecla company for its White Pine stamp-mill. Work at the plant is well ahead.

PLATTEVILLE, WISCONSIN

A Review of the Zinc and Lead Ore and Pyrite Situation in October.—Production of Ore and Ore Buyers.—New Plants.

October in the Wisconsin zinc-lead districts witnessed extremes in all phases of the industry. Prices for ore and metal at the beginning of the month were somewhat buoyed up by the smelter interests, who were given reason to believe that a large foreign demand for spelter might develop, but beyond

GALENA-TRENTON, THE ORE-BEARING FORMATION, AT MINERAL POINT, WISCONSIN.

inquiries nothing of importance developed. Agents for foreign interests were quoted prices in advance of that offered domestic consumers on attractive orders, but before the month had well advanced both home and foreign demand had settled down to low levels, and prices for spelter and ore went down accordingly. The lower and medium grades seemed to be in better demand, as shipments eventually proved that the higher grades were being withheld, until in the closing days of the month there was found at several points in the field a reserve considerably in excess of 5000 tons of concentrate. Prices ranged from the first of the month, on ore from $40 to $45 per ton for 60% ore, to $33 to $39 about the middle of the month, when there was an important closing at about $40 per ton. Spelter closed at $4.75 per cwt., East St. Louis, with business exceedingly dull. Production of raw ores for all districts was well maintained, and deliveries in and out of the field set up a fair record as compared with previous monthly reports. New buying interests invaded the field, stimulating competition somewhat in the southern districts, which made the far better showing of the month over the northern parts, where production was light and sales covered only a portion of the ore offered for sampling. Carbonate of zinc ore producers were practically shut out of the markets all the month, and carried over a large tonnage, which began moving after the first of November. Prices were good, in fact better than quoted in years, but the demand was limited.

Lead ore was in poor demand, and quotations on both metal in pigs and ore reached lower levels than had been reported in years. Production was curtailed and shipments very small.

Pyrite suffered in reduced markets, and production was much lower than usual. A new buying firm failed to stimulate competition or increase production.

The following deliveries were made during the month from the different areas of the field:

District.	Zinc, pounds.	Lead, pounds.	Pyrite, pounds.
Benton	7,790,000	60,000	2,254,450
Galena	4,868,000	65,000	.....
Cuba	4,134,000	.....	783,500
Hazel Green	3,972,000	.....	.....
Livingston	2,524,000	.....	.....
Shullsburg	1,856,000	35,000	.....
Linden	1,316,000	128,000	160,000
Platteville	1,180,000	.....	.....
Dodgeville	544,000	.....	.....
Highland	470,000	.....	.....
Harker	462,000	.....	.....
Montfort	168,000	.....	.....
Mineral Point	56,000	.....	.....
Totals	29,340,000	288,000	3,197,950

The gross production of raw ore from all mines for the month totaled 26,244,100 lb. This showing was made with producers purposely running short time about half of the month. Net refined ores to smelter and shipments of wet concentrate direct totaled 17,814,150 lb. The Mineral Point Zinc Co. delivered 55 cars or 4,152,430 lb., of calcined zinc ore to the Nassau Works, De Pue Illinois; one of the best month's turn-ins of the year.

Distribution of sales among the buying concerns represented in the field were as follows: to Mineral Point Zinc Co., 5000 tons; Grasselli Chemical Co., Cleveland, Ohio, 1484 tons; National Separating Works, Cuba, 1106 tons; Empire Roasters, 888 tons; Illinois Zinc Co., 713 tons; M. & H. Zinc Co., 377 tons; American Metals Co., 574 tons; Linden Zinc Works, 315 tons; Campbell Separators, 160 tons; and American Zinc Co., 163 tons.

The West Hill Mining Co. 'tuned up' a new plant in the Platteville district, and was recovering 5 tons of zinc concentrate per day at the close of the month.——The Wisconsin Zinc Co., in the New Diggings district, started a 600-ton plant and was breaking a car of ore daily by the first of November. ——The New Jersey Zinc Co. commenced operating a new plant, costing $35,000, on the Penna-Benton mine at New Diggings. Numbers of miners' cottages were also added.——The Fields Mining & Milling Co., of Chicago, appropriated $50,000 on October 22, to be made immediately available for development and equipment of the new Thompson mine in the New Diggings belt. Considerable drilling proved a large deposit of zinc ore 60 ft. thick.——The Cleveland Mining Co. is now running a new $50,000 equipment on the Lawrence mine in the Hazel Green district.——The North Unity mine was opened and a new $30,000 plant started at the close of the month. This mine is on the northern limits of the Galena, Illinois, district. Longhenry Bros. were engaged in financing a new surface equipment for their mine in the Benton district late in the month. An option had been secured on an idle plant.——The New Jersey Zinc Co. put a new concrete and steel equipment into active service on the Little Coker mine in the Mifflin district. In the same district the B. M. & B. Mining Co. reconstructed a plant purchased from the Slack

Mining Co., on the new Biddick mine recently developed in this district.

Heavy consignments of zinc-bearing ores were delivered near the end of the month at the Mineral Point Zinc works from Mexico, and a train of 25 cars was unloaded in a single day. The business increased so rapidly that a deputy collector of import duty was reappointed and stationed at this point.

Drilling with steam outfits was under way in the Montfort, Benton, Hazel Green, and Shullsburg districts during the month with fairly good results in the second and third named areas. At Shullsburg, the McMillan Mining Co., of Milwaukee, being satisfied with results, has decided to provide a $50,000 equipment.

LEADVILLE, COLORADO

DEVELOPMENT OF LEADVILLE'S DEEP LEVELS.—TWIN LAKES AND LACKAWANNA DISTRICTS.

The big factor in the mining activities of the Leadville district at present centres around the unwatering of the down-town mines, as mentioned from time to time in the news section of the *Press*. The project has been brought to a successful termination after months of ceaseless endeavor on the part of Jesse F. McDonald, ex-governor, and promoter of the scheme, and his associates in the enterprise. Sufficient capital to finance the work has been secured, and is in the bank here. All of the ground that is desired by the pumping company has been signed over on long-term leases. The best centrifugal electric pumps have been ordered from the Providence Engineering Works, of Providence, R. I., and the motors are to be delivered by the General Electric Co. Neither concern has contracted to have the machinery on the ground before the first of the year.

Mr. McDonald was in the city recently and stated that everything pointed to an earlier start in actual pumping than had been supposed. The machinery is expected to arrive about the end of December.

The unwatering of the down-town area will be the first of a number of similar enterprises which will be undertaken in this district in the near future. The mineral deposits, which are known to exist in the down-town basin, while extensive in proportion, are not as rich as those that underlie Fryer and Iron hills. Propositions are on foot to unwater both of these places, and the former is reported to be all but completed. Leadville is looking ahead to the time when all three territories will again be producing a large tonnage of silver, lead, zinc, and iron ores. Each one of the schemes would give employment for nearly 1000 men, and at the same time offer many opportunities for the lessee to secure certain ground. It has been said for years that deep mining in the Leadville district would be more profitable than in the upper workings. This theory is about to be tested, and by this time next year there will be a marked change in conditions.

The Twin Lakes and Lackawanna districts continue to prove the best new areas in this territory. This winter will find three large properties producing high-grade ore for the first time in many seasons. The Mt. Champion, Lackawanna Belle, and Miller mines are all employing men on extensive orebodies. Milling processes have been arranged for the handling of the poorer ore, but so far very little has been treated. The efforts of the companies have been directed toward getting out all the rich ore possible, while prospecting the veins and the other ore has been allowed to stand. Preparations are being made by the Miller and Lackawanna Belle people to go into milling extensively next spring. They will confine the winter work to the high-grade ore, which averages about $400 per ton.

There is one new shaft being put down on Fryer hill which will be known as the Davis shaft. The manager, W. J. Davis, is sinking to cut the ore-shoot which was mined in the Matchless and Chrysolite properties in the early days. The shaft is now down about 100 ft., and appears to be at the bottom of the wash.

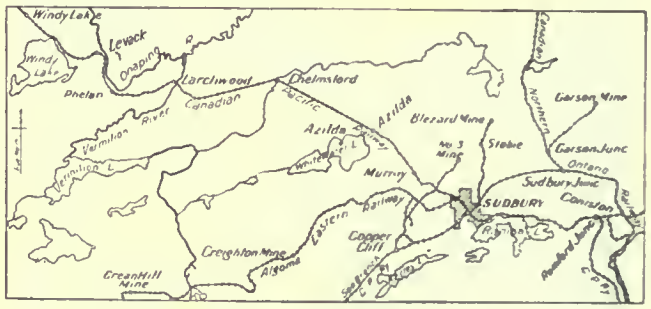
The low price of metals has a quieting effect on mining in the district, but no serious results have materialized as yet. With the chief output of Leadville centring around silver and zinc, the price of those metals is being closely watched.

TORONTO, ONTARIO

DISCUSSION OF THE NICKEL INDUSTRY AND THE EFFECT OF THE PROPOSED EXPORT DUTY ON MATTE.

Although mining operations in Ontario were considerably affected in August and September, conditions are again becoming normal. All the producing mines of Cobalt are now working, and although a further drop in the price of silver has meant decreased profits, there has been no falling off in output.

The copper-nickel companies of the Sudbury district were affected to a greater extent than any others, on account of the entire consumption falling off for the time being. The New Jersey refinery of the International Nickel Co. was closed altogether, while the mines and plant at Copper Cliff were run at only 33% capacity. Since then a revival of the demand for nickel has been experienced, and as a consequence, work has again been started at the refinery, while the output from Copper Cliff has been increased to 75% of its former capacity.



MAP SHOWING THE NICKEL DISTRICTS OF ONTARIO.

Owing to the fact that the Sudbury region is the chief source of the world's supply of nickel, and the International company the largest producer, which is controlled by American capital, there has lately been agitation in certain of the Canadian papers for a greater control of the source of supply, and for the placing of an export duty on the matte, as was provided for by an act passed some years ago. If this act were to become a law, it would mean that the nickel would have to be refined in Canada. This agitation is, of course, an outcome of the war feeling, and is due to the fact that Germany and Austria have drawn their supplies of nickel for armament from a British colony. Such agitation under the circumstances is ill advised, and should it be carried far enough, might work harm to a company that annually distributes in Canada millions of dollars in the form of wages, transportation charges, and payment for supplies.

When the International company was first formed, the refining of the matte, a secret process, was done by the Orford Copper Co. of New Jersey, which was a separate concern. The nickel company spent large sums of money in attempts to refine the matte itself, but was unable to evolve a process as satisfactory or as economical as that used by the Orford company. Eventually in order to acquire a satisfactory process for itself and to protect its own interests, it was forced to buy the Orford company. The plant, which is most advantageously situated as regards shipping facilities,

raw materials, labor, power, and market, and representing as it does an enormous expenditure for buildings and equipment, would, in the event of an export duty being placed on shipments of matte from Canada, have to be dismantled and a new plant be built. The matter is one that requires serious consideration, and a thorough study of all the facts before any action is taken.

In time of peace it would be practically impossible to prevent the sale of nickel to any country that desired to purchase it, and in war time the International company can be depended upon to conform to the interests of the country from which it draws its supplies of raw material. As a matter of fact, all foreign shipments of refined nickel at the present time are known to the British government.

During the period ended October 7, the Hollinger, at Porcupine, produced 18,132 tons of ore averaging $13.54 per ton. Mining cost $2.08 and milling $1.23, and all costs totaled $4.41 per ton. The gross profit was $149,798. The surplus stands at $1,100,755.——The Associated company, of Kalgoorlie, Western Australia, has completed payment on the North Thompson property.

Ore shipments from Cobalt in October totaled 1281 tons from 16 properties.——The Nipissing high and low-grade mills treated 171 and 7009 tons of ore, respectively, yielding $200,384. The refinery shipped 630,846 oz. silver. The 'hydraulic prospector' uncovered five veins. Driving east at 900 ft. from No. 64 shaft was continued to 300 ft. in low-grade ore. A winze is to be sunk 100 ft. on the vein.——The Crown Reserve company will pay a 2% dividend on December 15, equal to $35,276. This makes a total of 334% and $5,936,126 since 1908. This Company's Porcupine Crown mine is paying 3%, $60,000, per quarter.

AUSTIN, TEXAS

Mining in Western Texas.—Sheridan Copper Mine.—Asbestos, Mica, and Quicksilver Deposits.—Metal Output.

More prospecting and actual mining development is now going on in the mountains of western Texas than for several years. This condition is accounted for partly by the fact that many of the men who were formerly owners or employees of mines in Mexico have been forced to leave that country, and are taking up properties on this side of the Rio Grande. The new mining law is also causing an increased activity in locating claims upon state lands.

In the Shafter district, the old producing silver mine that is owned by a syndicate of California men continues to keep up a good record of production. It has been worked for about 33 years. Several new claims are being developed nearby.——Favorable reports also come from the mines in the vicinity of Van Horn and in the Davis mountains.

Advices have been received here from the Burnet district that the Sheridan Copper Co. is doing development work on a group of eight claims and sixteen prospects. The Company has opened a vein of copper ore that averages 3.5%, with rich occasional shoots. Plans are also on foot for exploiting, on an extensive scale, several asbestos and mica properties in the Llano district.

Comparatively little is being done in the Terlingua quicksilver district, situated in Brewster county, 80 miles south of Alpine. Two or three of the older mines that have been closed down for several years, would have been reopened within the next few months but for the fact that the existing financial condition has interfered with the plans of the owners, it is stated.

According to the U. S. Geological Survey, the metal output of Texas in 1913 was as follows: gold, $340; silver, 427,553 oz.; lead, 225,227 lb.; copper, 34,665 lb.; and spelter, 652,607 lb., with a total value of $310,411, compared with $269,274 in 1912.

SILVER CITY, NEW MEXICO

Lordsburg, Santa Fe, Florida Mountain, White Oaks, and Socorro County Districts.—Meerschaum Mining.—Lead and Copper Ores.

The Eighty-Five Mining Co., at Lordsburg, is again shipping to the Douglas smelter, as well as other operating companies in the district.——The Green King mine has encountered water at 40 ft. in sinking, and a 4-ft. high-grade vein has been opened.——Higgins and Scarborough, Haydan and Weldon, and others, are now extracting ore in the Shakespere area.——The Bonnie Mining Co. is again active.

Two properties were sold recently by receivers at Santa Fe, in Santa Fe county. George Heineman, of Kansas City, Missouri, has purchased the patented claims of the American Gold-Copper Mining Co., at Bonanza, for $3168, and Frederick K. Gilbert has acquired the turquoise mines of the American Turquoise Co., at Cerillos, for $24,000.

In the Florida mountains, 16 miles south of Deming, Luna county, Manuel Pana and associates have opened a good body of zinc carbonate ore, and shipments are being made. It is said to assay 37% zinc, 18.5% lead, and 12 oz. silver.——C. P. Cramer, of Georgetown, is reported to have opened a good body of similar ore.

The Parsons Mining Co., at Nogal, Lincoln county, is preparing for operation and is purchasing equipment. An adit in the Hopeful claim has opened a vein assaying from $4.80 to $13 gold per ton.——The entire White Oaks area is active.

The Tri-Bullion mill of the Empire Zinc Co., at Magdalena, Socorro county, is undergoing reconstruction, which will result in a practically new plant.——The Ozark Smelting & Mining Co. continues to develop ore.

LOADING MEERSCHAUM FROM AMERICAN MEERSCHAUM & PIPE CORPORATION'S MINE IN THE ALUNOGEN DISTRICT.

Mines 30 miles north of Silver City have produced several hundred thousand pounds of meerschaum, and, owing to the war, further development is probable. The property of the American Meerschaum & Pipe Corporation was operated continuously for 10 months during 1913, but on account of impractical methods in the Eastern factory and the failure to carry on work at the mines in a systematic manner, the Company went into the hands of a receiver. There is ore in the mines, and several commercial veins of the mineral lie undeveloped in the district. A complete mill for the treatment of meerschaum was erected.

The bulk of the smelting lead and copper ores and concentrates of this state continues to be shipped to the El Paso smelter. Some is sent to Pueblo and Salida, Colorado; also to Douglas, Clifton, Needles, and Cananea. Bullion and matte go to the Omaha refinery, and bullion to Selby. Zinc ore and concentrate go to Kansas, Oklahoma, Wisconsin, Illinois and Eastern plants.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

The report of Sumner S. Smith, mine Inspector for Alaska, covering the fiscal year ended June 30, 1914, has just been published in Washington, D. C. It covers 36 pages and includes the following notes: Practically all parts of the territory were visited. W. Maloney was appointed an Inspector for the second and fourth divisions, with headquarters at Nome. The office of the inspector for Alaska requires more assistance and better housing at Juneau. The output of minerals was as follows:

Source.	Ore, tons.	Gold, oz.	Silver, oz.	Copper, lb.
Sllicious ores	1,614,506	232,917	30,897	.....
Copper ores	135,756	6,386	273,179	21,659,958
Placers	.....	516,645	58,487	.....
Total	1,750,262	755,948	362,563	21,659,958

The total value was $15,626,813, a decrease of $1,519,138 compared with 1912-13. Other topics discussed are lode mining, greater use of dredges, coal mining, railroads, labor conditions, accidents (15 killed in mines, 7 in placers, and 3 on dredges, or 25 out of 8000 employed, equal to 3.125 per 1000), length of mining season (125 to 170 days), cost data, and a list of mines and their operations. All interested in Alaska mining should have a copy of this report.

Fairbanks

It is reported that Fairbanks creek will be one of the busiest areas in the Tanana valley this winter, as prospecting and taking out dumps will be done by a number of operators. ——There has been a new discovery somewhere near the headwaters of the Tolovana river, and numbers of men have left for that place. The exact locality is unknown so far.

Juneau

A stope boss and a miner were killed, and a shift boss was injured at 2100 ft. in the Treadwell mine, on November 1, by gas asphyxiation. It is thought that a blast destroyed an air-pipe which should have freed the stope from smoke.

The Jualin mine has been closed for the winter. Arthur Reandeau was in charge of the property, which was financed by Belgian capital.

Nome

The steamer *Corwin* arrived at Nome from York during the second week of October, bringing 63 tons of black tin, mostly from the York Dredging Co. The vessel left for Seattle on the 15th.——People who wish to go to Dawson without passing over the open sea route to Skagway, will be able next season to travel to St. Michael and then up the river Yukon to Dawson, or *vice versa*. The steamer *Sarah* is now at Dawson and will make the first trip at the opening of navigation.

The *Nome Daily Nugget* has just published its 'Mining and Dredging Edition.' It consists of 84 pages, with numerous illustrations, and includes the following information: To October 7, gold worth $2,259,780 was passed through the local customs house, and about $80,000 through the post-office. This season's output is estimated at $3,000,000, compared with $2,486,778 last year. The total to date is $56,260,680. A directory of dredge companies gives 41 companies in the Nome, Council, Solomon, Teller, Inmachuk, Candle, and Kougarok districts. Hydraulicking and dredging are fully described as pertains to the Seward Peninsula. The tin industry seems to have a good future. Individual dredges, companies, and districts are described, and a chapter on the wreck and rescue of the Karluk survivors from the Arctic ocean completes an interesting publication.

ARIZONA

Cochise County

Driving on the vein on No. 8 level of the Commonwealth mine at Pearce has advanced 19 ft. east and west. In the latter drift is 6 ft. of $10 to $15 ore. On November 6 the 'old gold streak' was discovered in the old workings near B shaft. It was first cut on No. 5 level, gold showing in a decomposed porphyry. Similar ore was found on No. 6 the next day. During the last week of October the mill received 2111 tons of ore.

Gila County

The Old Dominion company, at Globe, produced 1,616,000 lb. of copper in October, compared with 2,121,000 lb. in September and 3,303,000 lb. in May.

The Ray Consolidated Copper Co., with a mine in Pinal county and smelter in Gila county, reports as follows for the quarter ended September 30: Owing to the copper market, a 50% reduction of output was decided on August 5. All men are being employed on alternate days. During the third week of September all work was temporarily stopped on account of a violent cloud-burst. Development amounted to 10,626 ft., making 448,945 ft. to date. Results were as follows at the mine and mill:

Details.	Third quarter of 1914.	Second quarter of 1914.
Cost of mining, cents per ton	54.867	61.741
Ore milled, tons	546,734	764,040
Average copper content, per cent.	1.691	1.786
Extraction, per cent	67.47	68.69
Copper produced, pounds	12,475,153	18,748,343
Cost of milling, cents per ton	45.85	47.24
Cost of production, cents per pound	8.738	8.541
Net profit	$420,922	$959,494
Dividends paid	.....	$545,358
Surplus over bond interest and dividend requirements	$420,922	$414,136
Copper on hand, pounds	26,405,739	25,819,674
Price of copper for quarter, cents per pound	12.4858	13.9198

A total of $2,708,000 par value of bonds was outstanding on September 30, 1914.

The 300-ft. stacks at the International smelter at Miami are finished. Construction of this new plant has proceeded steadily in spite of the depressed copper market.

Maricopa County

Fire on November 16 destroyed property worth about $300,000 at Phoenix.

CALIFORNIA

Conferences between the mine owners and the Industrial Accident Board have resulted in a proposal from C. W. Fellows, representing the latter, to accept mining risks on a merit rating system, with quarterly adjustment of premiums and a refund of all sums collected not needed to cover ordinary risk, cost of handling the business, and surplus for catastrophe risk. This offer is conditional upon the mining men interest-

ing themselves sufficiently to furnish business equalling $100,000 annually in premiums. The proposal is now before the executive committee of the California Metal Producers Association.

Butte County

The Leland Stanford University estate includes land near Chico, and on account of alleged damages to the land, the board of directors has filed suit in the Superior Court against the Butte Creek Consolidated Dredging Co. for an injunction prohibiting further dredging on Butte creek, northeast of Chico.

Inyo and San Bernardino Counties

Salines in the Owens, Searles, and Panamint basins of southeastern California is the subject of U. S. Geological Survey *Bulletin* 580-L, by Hoyt S. Gale. It covers 73 pages, and is illustrated by line-cuts and maps. The author states that the salt-incrusted valley floor commonly known as Searles

MAP OF SOUTHERN CALIFORNIA.

lake has lately come into prominence through the widespread interest in the search for an available source of potash in this country. The previous estimate of 4,000,000 tons of water-soluble potash salts has been confirmed by subsequent development. In discussing the lake history of the basins, each one is considered, as it played an independent part in the whole system. Water from Owens valley, the principal source of supply, passed through Indian Wells, Searles, and Panamint valleys, and probably finally into Death valley. The bulletin describes each area, the salts, crystalline forms of salts, and prospective commercial development.

Nevada County

Taxes paid to this county by the North Star company amount to between $16,000 and $17,000; Empire and Pennsylvania, $7000; and two lumber companies, $7000. These taxes represent 20% of those paid by the entire county.

Placer County

There is increased activity in mining in the Auburn district of late. The Mary Bell has been bonded to San Francisco people, and the Spanish Consolidated to San Diego men. Rich gravel is showing in the Excelsior drift mines, and 35 men are now employed.

Plumas County

It is reported in Quincy that placer mining claims of the Claybank Mining Co., near Slate creek, have been acquired by J. H. Thomas of La Porte, and Los Angeles people. A large restraining dam will be constructed to hold the débris, and hydraulicking started after a lapse of many years, having been stopped since the anti-débris law became effective.

San Bernardino County

(Special Correspondence.)—The mining of tungsten ores in this county is showing activity of late, and there is a probability that the output of this state will be somewhat increased during the current year. This will be due partly to the Atolia Mining Co. Early last spring the management started leasing claims to 'float diggers.' In a few weeks there were over 40 men in the vicinity of the Atolia, working new scheelite dry placers, which later led to a discovery of a network of scheelite and quartz veins. These placer deposits yielded a good tonnage of high-grade tungsten ore, especially near the Papoose mine, but were soon worked out. Following the placer work came discoveries of quartz veins which were the source of the rich 'float,' and those who had placer leases began developing new quartz deposits. The result was that the Atolia company discharged its miners, as the mill was being kept busy night and day on ore produced by lessees. This method has been in vogue all summer. Early lessees received $4 per unit of tungsten ($WO_3$), but later operators received only $3.50 per unit, less $6 over and above 3%. One dollar per ton royalty is charged by the Company, while lessees pay for all timbering, hauling, supplies, and help employed. Lessees cannot sublet, and the Company reserves the right to pay all help of lessees, which is deducted from ore produced by them, including 30c. per shift for each individual hired, as an accident insurance fund, under the state law.

The scheelite veins of this district are found generally in fault fissures, and while rich, at times up to 60%, are not continuous, making and pinching out without any indications. These conditions are discouraging to lessees, and during October the ore production fell considerably below the capacity of the Company's mill, and an additional force of Italian workmen was put to work again on the regular tungsten producing claims of the Company's property.

Quite a number of additional tungsten claims were located adjacent to the Atolia company's holdings during the past few weeks, some of which are promising. The California tungsten belt, that in which the Atolia mines are situated, is known to extend from Table mountain, 30 miles west of Barstow, through Cuddaback lake and Atolia, over and across the Rand mountains to its west side; thence west to Jawbone cañon, a distance of over 50 miles. Specimens from the cañon show a mixture of scheelite and a darker mineral, which is probably hübnerite. Those from the Sidney group, west side of Rand mountains, are speckled cream-yellow, and generally contain gold. Near Randsburg and the 'stringer district' are several tungsten ore-producing mines, both placer and quartz, nearly all of which appear to be increasing in production; but, in general, it is conceded that the Atolia district, as in former years will lead in tungsten production for 1914, owing to rich development in the Papoose, Plute, and adjoining claims, this summer.

Randsburg, November 4.

Sierra County

Rich ore has been opened in the Dreadnaught mine near Alleghany.——Two parallel veins are being developed in the Mammoth Springs, in charge of J. A. McGuire.——Rails and an air-pipe are being placed in the lower adit of the City of Six near Downieville.——A new pump is to be installed in the Telegraph.——Water is scarce for operating the Mt. Alta gravel claim on Oregon creek.——Considerable work is planned by W. Copeland for the Bald Mountain property.

COLORADO

Ouray County

Shipments from Ouray during October were as follows: Concentrates: Camp Bird, 591; Wanakah, 138; Atlas, 330; Cumberland, 11; San Juan Metals Co. (zinc), 20; Barstow (Lundberg lease), 12; and American Nettie mine, 10; a total of 1112 tons. Crude ore: Wedge mine, 250; Arps and Krisher, 27; Bachelor-Khedive, 31; and Wewissa, 40; a total of 348 tons; also 218 tons of matte from the Wanakah smelter.

The Camp Bird company made a profit of $42,000 in September.

Park County

(Special Correspondence.)—The well known London mine is being let out to lessees on the block system, which is now in vogue in the Ibex and New Monarch properties at Leadville. The London has produced high-grade gold, silver, lead, and copper ore right through, and every indication points to a still greater production from it and adjoining claims. All the ore that has been extracted to date has been found in the vein above the tunnel level. No work has been done below, although the ore-shoot continues to go down. The property at present offers a fine opportunity for capitalists who could finance the driving of another tunnel on the vein at a greater depth. The ground has been but little prospected. The ore was found near the surface, and all that was in sight or readily found has been mined, leaving one of the richest areas of mining ground in the state to be opened. There is no doubt that in the future the mine will show many interesting things about the formations in that territory.

Leadville, November 13.

San Miguel County

The Tomboy mill treated 12,610 tons of ore in October, yielding bullion worth $32,500, and concentrate valued at $46,500. The profit was $31,500.

Summit County

It is proposed to unwater a portion of the Breckenridge district, as at Leadville, and recover the ores now covered. ——The Wellington Mines Co. is shipping seven or eight cars of zinc concentrate per week to Bartlesville, Oklahoma.—— The Tonopah Placers and French Gulch dredging companies keep their boats fully employed.

Teller County (Cripple Creek)

Owing to the fire at the El Paso mine curtailing ore production for the Golden Cycle mill, the latter company will probably grant more leases in certain parts of its property. Only one lessee is working below No. 8 level, and so far the monthly output by lessees has been restricted to 5000 tons. A large number of applications are on file for leases in the deeper levels.——Stratton's Independence Co. reports as follows for September: Production, 4590 tons of ore averaging $5.75 per ton; low-grade mine and dump ore milled, 10,830 tons; working profit in milling department, $7554; loss in mine department, $950; and net profit to Company, $6604. ——Twenty feet of $8 to $10 ore has been opened in the upper levels of the Doctor-Jack Pot property. This mine produces 2000 tons of ore per month. L. G. Carlton is manager. ——The main shaft at the El Oro is being retimbered. Robert Mullen is manager.

IDAHO

Lemhi County

At 800 ft. in the Latest Out mine, at Gilmore, 7 ft. of high-grade galena has been cut.——A wide vein has also been exposed in the Allie.

Shoshone County

A comparison of the Coeur d'Alene monzonite with other plutonic rocks of Idaho is discussed by C. A. Stewart, of the University of Idaho, in *The Journal of Geology* for October and November. Until further theories are proved, geologists must be content with the fact that the Coeur d'Alene intrusives, and those northeast and southwest of them, are distinctly different from the average type of Idaho quartz-monzonite.

Twelve inches of galena, assaying 45% lead, has been opened in a cross-cut adit 1765 ft. long in the Nabob mine on Pine creek.——Development of the Calumet claims above Burke will be continued through the winter with M. J. Murphy in charge.——A Callow flotation plant is being installed in the Hunter mill, at Mullan, under the management of Otto Trojownowsky. The mill treats 1000 tons of ore per month, but this capacity is to be doubled.——A wide vein of copper ore has been opened in the Reindeer-Queen mine, east of Mullan. E. B. Crawford is manager.

The Caledonia Mining Co. paid 2c. per share last week, equal to $52,100. Revenue during July, August, and September totaled $248,286, and net profit $154,315. Mining cost $1.34, milling 46.6c., and loading for shipment 1.15c. per ton.

In the suit of the Marsh Mining Co. *v.* the Washington Water Power Co., for alleged discrimination of rates charged by the latter, the Public Utilities Commission failed to substantiate the charge, when the load factor was considered. Up to January 1, 1914, the Marsh company paid 1.13c. per kilowatt-hour, but the Bunker Hill and Federal companies paid only 0.8c. per kilowatt-hour, which rate was demanded by the Marsh company. In its defense, the power concern stated that charges and contracts are based on load factors, and an instance was shown in the case of the Hecla company's agreement.

KANSAS

Cherokee County

(Special Correspondence.)—Arrangements are being made by the New Century Mining Co., at Galena, to start its mill at an early date. A. D. Schriner, superintendent for the Company, stated on October 23 that in all probability operations would begin on November 1. The ground has lain idle for several years until a few weeks ago, when the present Company took charge, and after the installation of pumps began draining the lease. A 10-in. lift pump and a 3-in. force pump have been in operation for some time, and since lowering the water to the 90-ft. level, 13 new companies have begun operation on the lease, all of them having opened a rich shoot of ore assaying from 10 to 20% zinc. The mill, which will be in operation soon, is of 300-ton capacity.

O. W. Sparks and others, of Galena, have made another good discovery of zinc ore on their land at Klondike. They are at present treating the 'dirt' that is hoisted from the new mine with hand jigs, but expect to build a mill in the near future. The development is situated near the Yellow Pup and Yellow Jacket mines, which are on the same land, and have been large producers in the past.

One of the best finds that has been made for some time was that of Morlan and Co., who are operating in a shaft at the rear of the Blue Point building. The new Company has been prospecting for some time and hoisting dirt that will assay 20% lead. In the early part of the third week of the month, an unusually good face of ore was cut; 'chunks' of which, on being hoisted, weighed 375 lb. The ore is being worked at the 80-ft. level.

Galena, October 24.

MISSOURI

Jasper County

Output of the Missouri-Kansas-Oklahoma district for the week ended November 8 was as follows: blende, 7,941,210 lb.; calamine, 634,070 lb.; and lead, 1,186,030 lb.; averaging $41.52, $22.60, and $41.67 per ton, respectively. For 45 weeks the total output is: blende, 422,618,483 lb.; calamine, 27,235,190 lb.; and lead, 73,016,406 lb.; worth a total of $10,109,650.

MONTANA

The geological department of the University of Montana, at Missoula, has received apparatus for testing radioactive ores, and invites miners of the state to send specimens to the department for testing. No charge will be made. To supplement this addition to the department, a new set of 40 radioactive ores has been obtained.

Fergus County

During October, the Barnes-King mine produced bullion worth about $30,000 from 3955 tons of ore, compared with $23,035 and 5593 tons in September.

Jefferson County

The Elkhorn adit of the Boston & Montana Development Co. is in about 1050 ft., two Ingersoll machines being operated two shifts. A 10-in. air-pipe has been installed in the face. At 200 and 700 ft. in the adit, 2 ft. and 3 to 4 ft. of mineralized material was cut. The adit is to be driven 3000 ft., giving a vertical depth of 1200 feet.

Lincoln County

A steam-shovel is being assembled at the Bear Creek Mining Co.'s claims near Libby. F. Chapman is in charge of the work. Placer mining in the district is encouraging.

Silverbow County

The Davis-Daly Copper Co. reports as follows for the third quarter of 1914: Owing to the metal market, cross-cutting on the various levels of the mine was suspended in August. The shaft is down 2434 ft., and another 100 ft. is to be sunk. A station is being cut at 2400 ft. Just below the 2300-ft. level a vein was cut, which is probably that opened at 1700 ft. No mining has been done during the period. Development cost $41,488, and equipment and general expenses $5973. The recent assessment has yielded $220,000 to date.

Water has interfered with sinking at the Reliance mine, in the Moose Creek district, 18 miles south of Butte. A 50-hp. boiler, pump, and hoist are to be installed. D. M. Adams is president.

As soon as troops left Butte, union agitators got busy again, and have tried to get miners at the Speculator and Leonard mines to pay dues to the new union. Guards are still maintained at the mines, with searchlights on approaches.

Some rich copper ore is being extracted from the North Butte's Edith May vein at 2800 ft. The new hoist for the Granite Mountain shaft is being assembled. A 70-ton capacity traveling crane has been erected. The head-frame over the shaft is 450 ft. from the drums of the machine, and the wire rope will run on idlers on steel towers. The engine-room is 52 by 100 ft., and is completed. This hoist was described in the *Press* of December 20, 1913.

NEVADA

Elko County

A 50-ton mill, consisting of a Blake crusher, five 1250-lb. stamps, one 5 by 18 tube-mill, continuous decantation cyanide plant, zinc-dust precipitation apparatus, Bessemer gas-engine of 125 hp., and electric generator, is being erected for the Eastern Star Mining Co. in the Gold Circle district. E. Rheinhardt, of Winnemucca, is a director; and construction is in charge of W. B. Childester, formerly of Tonopah.

Esmeralda County

The Yellow Tiger Mining Co., Charles D. Wilkinson, manager, intends to replace the buildings and equipment destroyed by fire last week.——Gross production of the Jumbo Extension in October was $101,504, and profit $76,000. A dividend of 5c. per share will be paid on December 15.——Additional miners have been hired at the Silver Pick.——A mishap to the 6-in. centrifugal pump at 1750 ft. in the main shaft of the Merger has been repaired.

Humboldt County

An adit is to be driven by the Rochester Mines Co. to prove the orebodies at a depth of 1000 ft., also to afford a cheaper method of handling ore.——The Nevada Valleys Power Co. has started to construct a transmission line from Lahontan to Hazen, Lovelock, Oreana, and Rochester, a distance of 82 miles. The pressure of the current will be 60,000 volts. The installation will cost about $220,000.

Nye County

Eight mines in the Tonopah district produced 10,584 tons of ore, worth $206,472, last week. The following returns are for October: Belmont, 14,840 tons, yielding 319,489 oz. bullion and a profit of $120,465; Jim Butler, 2953 tons for $16,798 profit; and Tonopah Mining, 13,025 tons, producing 247,645 oz. bullion, and 58 tons of concentrate worth $24,585, giving a profit of $105,340.

A rise above 1100 ft. in the Extension has opened rich ore. This shoot has been found on three levels, and is 240 ft. long, and averages 10 ft. in width.

The Montana-Tonopah mill has been closed for 90 days on account of the silver market, or until the price of the metal improves, or higher-grade ore is opened. Development will be continued. The directors of the Company have made an interesting statement, and show that while from January 1 to June 30, 1914, 25,963 tons of ore was treated worth $10.16 per ton (silver at 57.59c. per oz.), the total cost was $7.74 per ton, from a recovered value of $9.55 per ton (94%), the profit being $1.81 per ton; and from July 1 to October 31, 16,545 tons was treated worth $6.57 per ton (silver at 48.25c. per oz.), the cost of $7.74 against a recovery of $6.18 per ton made a loss of $1.56 per ton, or $6456 per month. The ore has declined in metal content, and with silver at 57.59c. per oz., it is only worth $7.93 recovered, less $7.74 cost, leaving a profit of only 19c. per ton. Cash, bullion, and concentrate, and value of final clean-up were estimated on November 13 to be worth $64,318, while expenses to the 15th were $13,500, leaving $50,818 net.

At Tonogold, McNally and Mullins lease has a shaft down 30 ft., showing 5 ft. of formation, which yields quartz panning up to $75 per ton. A parallel vein has also been opened.——The Campbell and Kelly lease has shipped 240 sacks of ore to a small mill near Tonopah.——Many other claims are yielding good results.

White Pine County

Silver-lead ore is still being mined in the White Pine district, of which Hamilton is the centre. From the Jennie A. mine, in the mountains, ore is packed down, loaded on wagons, and hauled to Eureka. J. W. Nyce is manager. The Hamilton Power, Mining & Transportation Co. is also extracting ore from the Grand Prize claims and hauling it to Eureka.

During October, the Nevada Consolidated safety department recorded seven disabling accidents, causing a total loss of 48 days to the injured men. These accidents were mostly due to carelessness.

NEW MEXICO

Grant County

The Chino Copper Co. reports as follows for the third quarter of 1914: Like other porphyry copper mines, production at this one was reduced to 50% capacity early in August.

For the first time since starting work the smelters paid for gold in concentrate amounting to a credit of 0.1c. per pound of copper. It was expected that, owing to the curtailment of capacity, costs would increase, but two months' work shows that it has been possible to even reduce costs, all equipment being maintained at the usual high standard. The new primary crushing plant was started in August, and makes a product which can be conveniently handled on cars and at the mill. It has resulted in considerable economy. Only

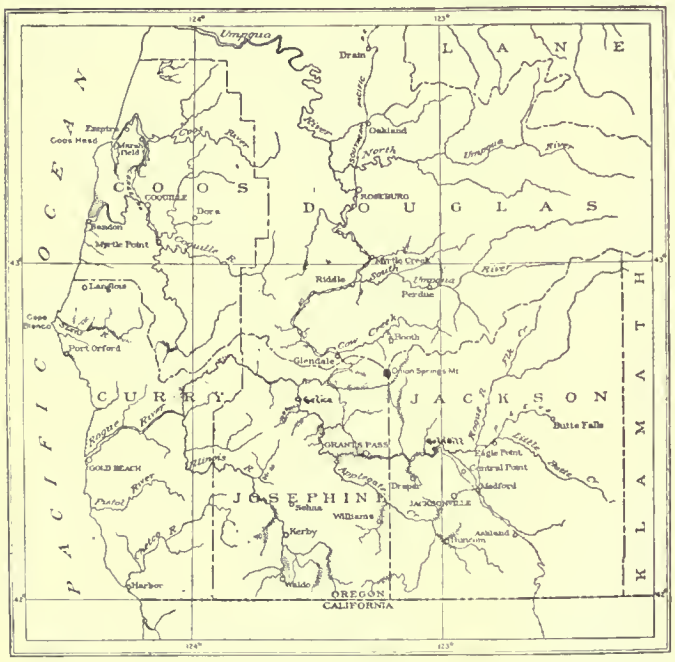
$1500 of first-mortgage bonds are now outstanding. The issued capital stock at the end of the quarter was 869,940 shares.

Details of operations.	Third quarter of 1914.	Second quarter of 1914.
Stripping removed, cubic yards..	702,223	1,119,805
Cost of removing overburden, cents per yard	32.75	30.71
Cost of mining, cents per ton....	21.78	20.42
Ore milled, tons	390,000	587,900
Average copper content, per cent.	2.165	2.165
Extraction, per cent	68.04	66.89
Copper production, pounds (including ore smelted direct)...	11,777,813	18,041,451
Cost of producing metal, cents per pound, net	7.37	7.49
Copper on hand, pounds	23,273,719	.....
Price received for metal, cents per pound	12.4344	13.9191
Total profit	$566,495	$1,102,104
Dividends paid	433,400	652,080
Surplus	133,095	450,024

OREGON

Jackson and Josephine Counties

The petrology and mineral resources of the above counties are described by A. N. Winchell in *The Mineral Resources of Oregon* for August, published at Corvallis by the Oregon Bureau of Mines and Geology. The work covers 265 pages, and is well illustrated. The field work on which the report is based was done during the summer of 1913. With the author were S. W. French, L. E. Reber, Jr., C. B. Watson, and Harley Hall. Many men in the various districts visited gave generous help, also the director of the state bureau mentioned, H. M. Parks. The investigations cover the location, topography, history, development, production ($16,314,633 since 1852), geology, mineral resources, ore deposits, mineral waters, coal, placer mines, gold quartz mines, copper, and future possibilities of the nine districts examined. A good index completes a useful work on the most important mining counties of the state.



MAP OF SOUTHWEST OREGON, SHOWING MINING DISTRICTS OF JACKSON AND JOSEPHINE COUNTIES. THE DOTTED AREAS SHOW AURIFEROUS GRAVELS (AFTER U. S. GEOL. SURVEY).

UTAH

The Commercial Club of Salt Lake City is endeavoring to help the metal producers, especially of copper, of the state, and has asked the Secretary of State, William J. Bryan, to take steps to arrange for the metal to be exported to neutral countries. It is pointed out that the welfare of Utah largely depends on its mining industry, which employs 16,560 people directly, and 50,000 indirectly, and pays $17,000,000 per year in wages, $4,400,000 in railroad freight, $10,000,000 for supplies, and $600,000 in taxes. Out of 10,202,000 tons of ores, worth $44,800,000, in 1913, 9,700,000 tons contained copper. The resolution of the club was signed by the following men of Utah: C. W. Whitley, American Smelting & Refining Co.; C. H. Doolittle, Bingham-New Haven C. & G. Mining Co.; F. G. McGanney, Hercules Powder Co.; C. N. Strevell, Independent Coal & Coke Co.; George F. Waddell, Ohio Copper Mining Co.; William Wraith, International Smelting Co.; H. G. Williams, Utah Fuel Co.; F. R. Sands, Bingham Mines Co.; R. C. Gemmell, Utah Copper Co.; George W. Heintz, United States Smelting, Refining & Mining Co.; E. E. Calvin, Oregon Short Line Railroad Co.; S. V. Derrah, Denver & Rio Grande Railroad Co.; J. H. Manderfield, Salt Lake Route; P. B. Sawyer, Utah Power & Light Co.; and John Dern, of the Lower Mammoth, May Day, and Uncle Sam mining companies.

Utah mines paid a total of $275,657 in dividends during October.

Beaver County

Nearly 1000 mining locations have been made in the east part of this county during the past summer, against 240 last year. This shows considerable activity, especially in gold-bearing areas.——A new shoot of rich silver-lead ore has been cut in the Moscow mine. On the 800-ft. level is 4 to 5 ft. of ore assaying 100 oz. silver and 40% lead.

Juab County

At 700 ft. in the Lower Mammoth mine there has been opened 3 ft. of ore assaying 4% copper, 13 oz. silver, and 50c. gold per ton. This development was in the unprospected part of the property.——The Chief Consolidated company is negotiating for the purchase of the Scotia claims, west of Tintic. The mine has shipped over 16,000 tons of ore to date.——Work has been started on ore at 1400, 1600, and 1800 ft. in the Chief.——A shipment of 35 to 40% lead, 15 oz. silver, and $1.50 to $2.50 gold ore has been made from the 1200-ft. level of the Tintic Standard.

Salt Lake County

The Alta Tunnel & Transportation Co.'s adit is in nearly 1000 ft. into the divide between Big and Little Cottonwood cañons. About four or five feet is being driven daily in hard blue limestone.——Four miles south of the Utah Copper Co.'s Magma mill the Hercules Powder Co. is erecting a plant, which is 95% completed. It consists of between 150 and 200 small buildings, made necessary in the manufacture of dynamite and black powder. The quantity to be made is 1,000,000 lb. and 500 to 1000 kegs per month and per day, respectively. There will be 200 men employed when in operation.

Summit County

The new Daly West mill is in operation, treating second-class ore. F. W. Sherman is superintendent.

Ore shipments from Park City in October were as follows: Silver King Coalition, 2301; Daly-Judge, 2525; Silver King Consolidated, 254; Daly West, 154; Thompson-Quincy, 12; Little Bell lease, 21; Creek jiggers, 42; and Mines Operating Co., 70; making a total of 5379 tons.

CANADA

Alberta

Seventeen wells are being sunk in the Calgary oil belt, and nine in the Sweetgrass area of this province and the state of Montana.

YUKON

Three of the Canadian Klondyke company's boats were operating on October 23. C. A. Thomas is resident manager. Good progress is being made in raising No. 2 dredge which

OFFICE OF THE YUKON GOLD CO., DAWSON.

aunk in October. The Yukon company's hydro-electric power plant on the Twelvemile river closed down on October 23, having operated since May 9, or 167 days. This plant contains three 625-kw. generators. R. E. Franklin is electrical superintendent, and Warren Macfarland is in charge of the ditch.

COLOMBIA

During the week ended October 27, the Pato dredge handled 50,750 cu. yd. for gold worth $28,000.

NICARAGUA

(Special Correspondence.)—The manager of the Javali and Escandalo Mining Co., Ignatius O'Reardon, left for New York last week to purchase machinery for the new 150-ton cyanide plant to be installed at Javali. George Fairbairn, formerly manager of the Babilonia Gold Mines, Ltd., left recently for London. He is succeeded by J. P. Lake. The new slime plant is now in operation. Arthur Feust, superintendent of the Cedro mine, is expected to return from New York shortly.

La Libertad, Chontales, Nicaragua, October 17.

Obituary

ROBERT B. ESTEY, veteran mining man of Leadville, died on November 2, after a long illness. He was born 79 years ago at Calais, Maine, and went to Colorado in 1879.

PATRICK J. HOLLAND, well known as a practical and efficient mining foreman at Grass Valley, died on November 5. He was 45 years old and had been in the district for 21 years. His death will be regretted by his many friends.

HENRY GANNETT, who died at Washington, D. C., November 5, was one of the best known modern geographers. Born in Maine in 1846, graduating at Harvard in 1869, connected for a time with the Harvard Astronomical Observatory, he finally found his real vocation when he joined the Hayden Survey as a topographer. When that organization was merged with others to form the U. S. Geological Survey, Gannett soon became a geographer and as such had charge of many important surveys. For a time he was chief geographer, which position he gave up to take up studies connected with the census. In this work he found congenial occupation, not only in the United States but the Philippines and Cuba. His acute analysis of the figures obtained won for him high rank in geographic circles. Gannett was a powerful influence in promoting the work of making a topographic map of the whole United States and his broad scholarly knowledge of geography made him a most helpful consulting man to many government bureaus aside from the Survey. A man of clean life and fine spirit, he leaves many friends.

PERSONAL

E. B. KIRBY is in New York.

HOWLAND BANCROFT is in Boston.

COREY C. BRAYTON is back from Nome.

SEELEY W. MUDD has been in San Francisco.

H. V. WINCHELL was at Grass Valley recently.

VAN. H. MANNING was in San Francisco recently.

F. J. DENNIS is visiting CHARLES JANIN at Rancho Marcelino.

R. G. CASEY, JR., is going to the front with the Australian troops.

GEORGE H. GARREY was in San Francisco, returning from British Columbia.

FRED T. GREENE was in San Francisco, returning from Arizona to Butte last week.

G. H. BOLIN was reëlected mine inspector of Arizona at the elections on November 3.

THEO. H. M. CRAMPTON is making a detailed examination of some gold properties near Kingman, Arizona.

E. CALLENS has resigned his position as director of companies on the Rand to join the French army.

RALPH S. RAINSFORD was married on Monday, November 9, to Miss MARGUERITE LE BRETON, of Washington, D. C.

REGINALD E. HORE, editor of the *Canadian Mining Journal*, was married November 10 to Miss RUTH MORRISON of Calumet, Michigan.

W. MACDONALD, formerly of the metallurgical staff of the Waihi company, New Zealand, and the Scottish Gympie company, Queensland, arrived recently in San Francisco.

F. J. H. MERRILL was stricken with paralysis while at Mecca, California, last Saturday. While his condition is not critical, he cannot yet be taken to his home in Los Angeles.

JOHN RYAN, manager of El Rayo mine in Chihuahua, Mexico, has been captured by one of Carranza's generals and is being held for a ransom of P50,000, according to JOHN M. CALLOW.

RICHARD KLEESATTEL, president and manager of the Diamond Consolidated Mines Co., has returned to Seattle from Dixie, Idaho, after having operated the Black Diamond mine all summer.

WILLIAM R. BOLLEY has resigned as superintendent of the Baltic Mining Co., controlled by the Copper Range Consolidated. ALBERT MENDELSOHN, for the past two years mining engineer at the Champion mine, has been appointed to succeed him.

Among those attending the 'home coming' dinner of the Mining and Metallurgical Society to F. W. BRADLEY, at San Francisco last Monday were Messrs. CHRISTY, HERSAM, PROBERT, DENNIS, MUDD, BAIN, BURCH, HYDE, CALLAHAN, DERBY, BLAKE, BENJAMIN, SHOCKLEY, MORRIS, MUNRO, SHORT, MERRILL, JUESSEN, LARDNER, SMITH, and CLEVENGER.

J. C. FARRANT, the European manager for the Hardinge Conical Mill Co., enlisted in the English army as a seaman and was among those missing after Antwerp fell. It is now learned that he is a prisoner in the Doeberritz detention camp near Berlin. Mr. Farrant is a member of the Institution of Mining and Metallurgy of London and of the American Institute of Mining Engineers.

Presidential delegates to the American Mining Congress to meet at Phoenix, Arizona, December 7 to 11, are: C. H. LINDLEY and H. FOSTER BAIN, San Francisco; WALTER DOUGLAS, Bisbee, Arizona; SEELEY W. MUDD, Los Angeles; L. D. RICKETTS, New York; WILLIAM B. PHILLIPS, University of Texas, Austin; JOSEPH A. HOLMES, director of the Bureau of Mines; GEORGE OTIS SMITH, director United States Geological Survey, and HENNEN JENNINGS, Washington.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, November 19.

Antimony	15 —15¾
Electrolytic copper	12½—12¾
Pig lead	4.15— 5.10
Quicksilver (flask)	$55
Tin	34½—36
Spelter	6½— 6¾
Zinc dust, 100-kg. zinc-lined cases	10

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, November 19.—Copper is strong at 11.75c., with good domestic demands, lead strong and advancing at 3.70c., and spelter firm at 5c. per pound.

November 12 (delayed in transmission).—Copper, firmer with good domestic demands for current requirements and the future, 11.25c.; lead, strong, at 3.50c.; and spelter, quiet at 4.85c. per pound.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58 52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.13	Dec.	57.73	....

The following shows the course of prices in New York and London during the week: 48.25, 47.62, 47.62, 48.87, 49, and 49.75c.; and 22.31, 22.12, 22.12, 23, 22.75, and 22.87d. per ounce. By the steamer 'Korea' from San Francisco, on November 14, silver worth $480,828, say 1,000,000 oz., went to Hongkong and Shanghai. Shipments from London to the East for the year, to October 29, were £4,721,500, against £9,263,500 last year, or about 45,000,000 oz. Bullion is being stored at Cobalt, the first shipment for two weeks leaving on November 13, amounting to 95,508 ounces.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slighly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Monthly averages.

Week ending			Week ending	
Oct. 22	50.00	Nov. 5		55.00

May	49 10	33.29	Nov.	39.77	....
June	45.10	30.72	Dec.	37.57	....

Tin is dull at 32 to 32.62½c. for 5-ton lots, and 31.75 to 32.25c. for 25-ton lots. London quotations are £127 10s. for spot, £137 for futures, and £141 per ton for Straits. The Vulcan Detinning Co., for the quarter ended September 30, reports sales totaling $203,729, and a deficit of $7533, against a loss of $30,532 for this period of 1913. The present surplus is $382,790.

COPPER

Prices of electrolytic in New York, in cents per pound.

Average week ending

CYANIDE

The situation regarding cyanide is clearing. H. A. Metz, of the House of Representatives, has been appointed to act with the German ambassador as a committee to receive bonds of importers, against re-export of cyanide and dyestuffs received from Germany. Bond must be given for the amount of the invoice. Shipment of cyanide to Mexico will be permitted, in fact Roessler & Hasslacher are reported to have shipped 1000 tons from Rotterdam to Mexico, but no dyestuffs may be re-exported, and no cyanide except to Mexico. For the present, at least, Germany has not consented to shipments to Central or South America. The Roessler & Hasslacher Chemical Co. is building an addition to the Perth Amboy plant and expects, after January 1, to be able to supply everybody. In the meantime further small shipments from Germany are to be anticipated. Charles Butters, who has been keenly interested, has received by cable an offer from Rotterdam of cyanide to be shipped in American bottoms, at a price which figures to 16c. per pound for 100%. This is higher than the contract made by the Nevada Mine Owners' Association for 1915, which called for 120% at 15⅜c. per pound, only 1c. above the 1914 price. Small second-hand lots are still available, and thanks to the good sense of all concerned, no real distress has yet resulted in the United States, though in Mexico mills that might otherwise have resumed are idle. In Japan few of the gold mines have been able to continue operations and there is a real cyanide famine. The steamer 'Sun,' with 1000 tons of sodium cyanide for Roessler & Hasslacher was expected in New York November 20.

The Copper Situation

Interest continues keen in the probable outcome of the situation created by the attempts of Great Britain to prevent copper reaching Germany and Austria, in which it has taken the high-handed method of stopping shipments, to any other country, which are not definitely proved to be retained in that country. The copper on the *Kroonland*, which carried 3,158,400 lb., the *San Guglielmo*, with 1,568,000 lb., and the *Regina d'Italia*, with 705,600 lb., was removed at Gibraltar, and the vessels allowed to proceed to the Italian ports to which they were bound. The *Ascot*, carrying 3,759,160 lb. copper, has been ordered before the British prize court. The principal copper-selling agencies who first made a protest to the State Department have engaged John Basset Moore, formerly solicitor for that department, to present their case, and the matter was taken up this week. The Chambers of Commerce at Butte and Anaconda have sent a memorial to President Wilson in the following words: "Such narrowing of foreign markets, with the recent restricted demand in this country, will render impossible the continuance of our copper production even at the present curtailed rate, will close our mines and smelters, the main industries of Silverbow, Deer Lodge, and other counties of Montana, and so restrict the labor demand as to entail most serious disaster to these communities."

The British ambassador, Sir Cecil Spring-Rice, has been in conference with the State Department, and it is announced that copper consigned to Italy for home use will not be subject to seizure, but copper which has been consigned to a belligerent country or to order will be subject. The Italian government has prohibited the export of copper from Italy, but not the transit of copper through Italy to a foreign country. However, it is not likely that copper producers would care to chance the transportation through Italy of copper consigned to a German consumer. Copper producers must give assurance that metal shipped to Italy is for home consumption, and not for reëxport to Germany or Austria. It is said that arrangements have already been made for the transfer of copper to Switzerland through Italy. Switzerland is expected to become a large consumer of copper during the war period. Norway, Denmark, and Sweden have given satisfactory assurances to Great Britain, and it has been announced that consignments to named consignees in those countries will be passed by the British patrols without question.

The steamship lines have now taken fright and refuse to accept consignments of copper to Italy and Holland, and the government war risk bureau also refuses to insure shipments. Exports of copper to Europe in the past 10 months have been as follows, in pounds:

To	1914.	1913.
England	155,962,240	104,944,000
France	112,712,320	122,449,600
Germany	198,132,480	275,963,520
Holland	131,969,600	144,506,880
Belgium	6,442,240	4,941,440
Austria	30,932,160	31,050,880
Italy	43,480,640	35,562,240
Miscellaneous	21,911,280	2,755,200
Total	701,542,960	722,173,760

Shipments during 29 days of October were as follows:

To	Pounds.
England	20,932,800
Italy	16,387,840
Holland	4,099,200
France	4,005,120
Miscellaneous	7,022,400
Total	52,447,360

BOOK REVIEWS

IGNEOUS ROCKS AND THEIR ORIGIN. By Reginald Alsworth Daly. 563 pages. Ill., index. McGraw-Hill Book Co., New York, 1914. For sale by the *Mining and Scientific Press*. Price $4.

In this volume Mr. Daly has brought together, in revised and extended form, the substance of the series of brilliant papers on igneous rocks that he has published in the last dozen years or more. In doing so he has added to the already deep obligations of his fellow-workers to him, and has at the same time made the material available to the general public. What the igneous rocks are, their relative abundance and the significance of their distribution, the forms in which they occur, and the processes through which they have come into their present position, all these are subjects of fascinating interest to both layman and scientist. There is no one who has attacked these problems more vigorously than the present Sturgis Hooper Professor of Geology at Harvard. His conception of overhead stoping as a means of ingress of igneous masses to the crust of the earth has proved extremely fruitful and is only one of the valuable concepts for which geologists stand in his debt. The layman will be glad to find in this book that after all these years of extreme specialization in petrography, the old names and the old rock groups maintain a place, and Mr. Daly's demonstration of the overemphasis that has been placed on minor phases of rock differentiation clears the way to focusing attention on the really big problems of rock genesis, and it is the big problems that have the widest interest.

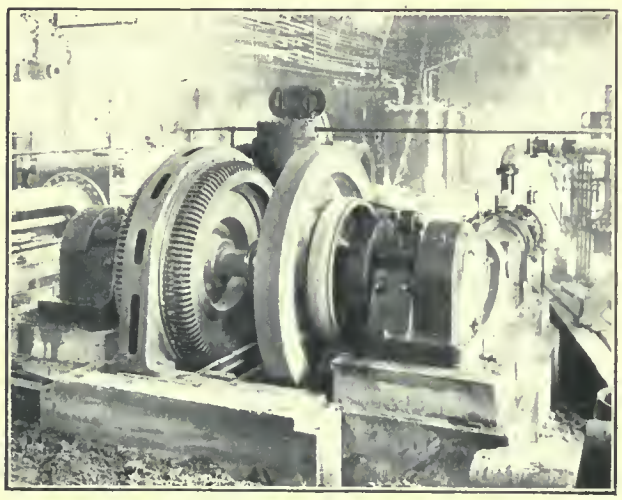
PRACTICAL STAMP-MILLING AND AMALGAMATION. By H. W. MacFarren. With a chapter on 'Arrangement and Construction Costs of Stamp-Mills' by Charles T. Hutchinson. P. 231. Ill., index. Published and for sale by the *Mining and Scientific Press*, 1914. Price $2.

This is the third edition of the work of 166 pages which first appeared in July 1910 and was well received. The volume under review is an entire revision and enlargement, and includes 77 carefully selected cuts and drawings. The first edition was not illustrated at all, so the value of the present book is considerably enhanced thereby. While there has been much said and written against the gravity stamp as an efficient crushing apparatus, and many machines tried to take its place, it may generally be said that it has held its own. This is mainly due to its simplicity, reliability, and wide range of adaptability. In Part I of this book is discussed in a practical manner the location and design of a stamp-mill, foundations, construction, details of the mortars, stamps, the latest stem guides, feeders, water supply, feeding ore, power absorbed, individual stamps, etc. This is entertaining reading for the millman. Amalgamation plays an important part in the treatment of free-milling ores, and the art is not learned in a day. Parts II and III cover the use of quicksilver in a mill, what affects amalgamation, how to remedy poor recovery, treatment of copper plates, and retorting amalgam and melting the resulting bullion. Also sizing and mill tests, sampling in the mill, all-slimings processes, mill crews, management, and disposal of tailing. Many men working small mines cannot afford to engage an engineer to advise on the cost and erection of a stamp-mill, and in Mr. Hutchinson's chapter on arrangement and construction costs of a plant, small operators will find a great deal to help them decide what is necessary. This discussion deals with several types of mills suitable, details of each part, advantages or disadvantages of jaw and gyratory crushers, lumber needed for buildings, foundations, and unforeseen costs.

New Machines and Devices

Compressor for the Vindicator Company

The big compressor being installed at the Vindicator property at Cripple Creek is of the type shown in the accompanying halftone. The machine was manufactured by the Sullivan Machinery Co., Chicago, and not by the Ingersoll-Rand company as noted in our news department in the issue of October 31. The machine here illustrated is a Sullivan class 'WN-2' direct-connected motor-driven unit of the cross-compound pattern. Its dimensions are as follows: low-pressure cylinder, 26 by 18 in.; high-pressure cylinder, 14½ by 18 in. The machine is operated at 120 r.p.m., and at that speed has a piston displacement of 1984 cu. ft. The compressor is driven by a General Electric 650-hp. motor mounted directly on the shaft of the compressor. This machine will operate at 10,000 ft. altitude. The motor is of the synchronous type and is



DIRECT-CONNECTED MOTOR-DRIVEN COMPRESSOR.

twice as large as the compressor requires. This extra large motor was purchased under a special contract with the power company for the purpose of correcting the power factor on its lines due to a large induction load. It is equipped with a fly-wheel to secure a smooth, even motion at all loads, thus keeping peak points in the load down. The frames are of the heavy duty pattern, the machine weighing about 45,000 lb. without the motor. The frames are provided with housings or hoods, and the cranks, eccentrics, cross-heads, etc., are thus protected from dust and grit. An automatic splash oiling system is provided. The intercooler is a vertical one, placed between the two cylinders and provided with a number of copper tubes through which the cooling water circulates. The intercooling space is unusually liberal. The valve motion on both high and low pressure cylinders consists of semi-rotary or Corliss inlet valves, one at each end of the cylinder. These are operated by eccentrics on the crank-shaft. The discharge valves are of a special automatic poppet type, and, like the inlet valves, are in the cylinder head. Some of these valves are set horizontally, but most of them are set radially around the edge of the head, so as to reduce the length of the pockets or ports leading to them and thus reduce the clearance in the cylinder.

The means for proportioning the load on the compressor to the demand for air consists in an automatic double-beat total-closure unloading valve, placed on the air inlet duct to the low-pressure cylinder. The high-pressure cylinder is provided with a relief valve, by means of which air remaining in the intercooler after the inlet unloader goes into effect is pumped out of the high-pressure cylinder. This it is claimed keeps the no-load power consumption down to a very low point.

Commercial Paragraphs

Western Electric Co., New York City. En Boletin S. 1. se muestran y describen las mejoras que poseen los actuales conmutadores de magneto de demlana capacidad y los cuadros distribuidores y de protectores.

Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pennsylvania, has recently issued a pamphlet entitled 'Central Power Stations in Coal Mines.' The catalogue is fully illustrated and contains considerable data on the power requirements of coal mines.

Percy Pitman, 25 Victoria St., Westminster S. W., London, England, has for distribution pamphlets descriptive of the fluid pressure governors for controlling the speed of water turbines, Pelton wheels, etc. The Company also manufactures a wide variety of Pelton wheels for different requirements.

Burd High Compression Ring Co., Rockford, Illinois, is distributing literature regarding the products of this Company. The high compression piston rings are made of a special mixture of the best gray iron and are adapted to air-compressors, gas, or gasoline engines, steam engines, pumps, and other machinery.

McCord Manufacturing Co., Detroit. An attractive booklet entitled 'Catalog No. 12,' is devoted to the McCord force feed lubricators for steam and gas engines, air and ammonia compressors, Diesel engines, and other machinery. The catalogue is fully illustrated and contains details as to construction and operation.

The Holt Manufacturing Co., Stockton, California, in Bulletin T. E. 61, discusses the use of the caterpillar tractor in road grading and heavy hauling operations. The machine is proving itself a valuable means for hauling wagon-trains on all kinds of roads, and is particularly adapted to work in soft and sandy soil where other machines would mire.

Siebe, Gorman & Co., Ltd., Westminster Bridge Road, London, England, has recently published a catalogue devoted to smoke helmets and first-aid equipment. The catalogue shows a large variety of apparatus and appliances particularly adapted to work in the mines. H. N. Elmer, Monadnock Bdg., Chicago, Illinois, is the American representative for this Company.

The Denver Engineering Works Co., Denver, Colorado, has for distribution Bulletins No. 1065 and 1066. Both of the bulletins are devoted to electric hoists—Bulletin 1065 to hoists with capacities of from 675 to 1600 lb. rope pull, and Bulletin 1066 to electric hoists with capacities from 2500 to 5000 lb. rope pulls. The smaller hoists are especially adapted for use in stopes or winzes, and they can be readily mounted on a flat mine car to serve as a portable hoist. The large hoists are made for both single and double drums. General specifications are given in the catalogue.

PERU exported copper to the value of over $8,000,000 in 1913. In August the copper smelters cut their output to about half normal capacity.

ANACONDA strategists are evidently following the lead of European war experts. With barbed-wire defenses capable of being charged with electricity, and a battery of searchlights as protection against possible Zeppelins of the Butte Mine Workers' Union, there seems little probability of the works being taken either by surprise or storm.

IQUIQUE correspondence in *The West Coast Leader* states that the nitrate production of Tarapaca was but 35 per cent of normal and for October not more than 40 per cent. As a result, 35,000 people had left the province and 3000 or 4000 were being supported by public and private charity. This is a radical change from normal conditions when, as Mr. Bancroft Gore showed in our issue of September 5, the labor supply is chronically inadequate.

CURTAILMENT of output has been the order recently in zinc mining as well as copper mining. It is difficult to get at exact figures, but the *Joplin News Herald* states that the local reduction amounts to 5000 tons per month, and estimates the total for the United States at 14,000 to 19,000 tons. While some ore is being imported and more offered, Siberian mines being the latest to make inquiries, it seems certain that prices of metal will be affected by the first of the year. The war is changing the zinc situation markedly.

MANUFACTURERS desiring to extend their trade in Argentina and Cuba are invited to send catalogues, preferably in Spanish, to the representatives of the National City Bank at Buenos Aires and Habana. They should be addressed 'For attention of Commercial Representative, Buenos Aires Branch the National City Bank of New York, 321 Calle Rivadavia, Buenos Aires, Argentina,' and 'Claude V. Allnott, Commercial Agent, Banco de la Habana, Habana, Cuba.' The bank also offers to furnish, through its foreign trade department, credit, information, and other proper facilities. Thus definite progress is being made in opening the way to sale of 'Made in the United States' goods in the countries to the south.

DIFFICULTIES over shipment of copper to neutral countries, discussed elsewhere, are in the way of adjustment. Mr. Thomas T. Read, New York editor of the *Mining and Scientific Press*, was in conference this week with the acting secretary of state, Mr. Robert Lansing, and officials of the department, with reference to the situation. An important announcement will shortly be made at Washington.

FLOTATION tests at Anaconda are proving so successful that it is extremely probable that the process will be adopted in place of leaching for treatment of current tailing. In that event the leaching plant now nearly completed will be used to treat accumulated material, while the Anaconda multiple-deck slime tables, followed by flotation, will be used on current material. Tailing of as low as 0.08 per cent copper content has been made with this arrangement.

DIFFERENCES between dredge recovery and the value of placer ground as indicated by drilling are puzzling and not easy to explain, if it be assumed that both prospecting and dredging be done with equal skill and care. There are instances on record of dredge recovery overrunning not only the average drill showing for the tract, a fact of no particular significance, but also the value indicated for the particular area dredged between clean-ups. On the other hand, the normal rule is that dredge recovery falls below the prospected value of the ground and in particular areas, as at Oroville, an average ratio, here 80 per cent, has been deduced from experience. Why this is true is probably to be explained oftenest by the relative fineness or coarseness of the gold. In close drilling, a sample rarely represents more than one part in 13,000. If the gold be fine it will evidently be more evenly distributed than if it be coarse, and accordingly there will be a larger chance of the gold getting into the sample. If we imagine all the gold contained in one acre of placer ground to be in one piece, the chance of finding it with a drill will be seen to be small, but the chance of missing it with a dredge almost equally small. It is a common experience to find larger particles of gold in the riffles than any in the drill sludge, and we believe this difference in probability of finding the mass is the explanation. It is therefore important in valuing placer ground to take into account the relative fineness of the gold.

LARGE claims have been made for the Reinohl process exploited by the American Rapid Cyaniding Company, and in connection with a test made at Ophir, Colorado, a few weeks since, the name of Mr. Walter L. Reid was used. Mr. Reid writes us that his observations on the test, which was conducted by a competent metallurgist of his acquaintance, convinced him that nothing was accomplished that could not be done at lower cost by several well known machines. He was in fact so unfavorably impressed that he declined to permit a test at the Smuggler Union mill.

GERMAN dealers, it has been said, are writing foreign correspondents that, in lieu of sending cash in settlement of bills due outside the Empire, the equivalent amount has been invested to the credit of the foreign firm in the German war loan at 5 per cent. We have been at some pains to secure an exact translation of such a letter received by one of our friends, and find that the statement is correct. In view of the numerous complications incident to international trade during war times, it is hardly appropriate to rest any preachment on the fact, but Americans and others should be fully informed so as to take proper precautions in selling abroad for the present.

COAL DUST firing is a method of burning fuel that permits of great economies and marked increase in thermal efficiency where it is applicable. Long ago it became the dominant method of applying heat to making portland cement clinker. More slowly it is finding a field in other industries, and just at present is rapidly making headway in copper smelting. Several years ago attempts were made to fire reverberatories at Cananea with coal dust, but with poor results. The main difficulty was that the ash blanketed the charge, and this failure has deterred metallurgists elsewhere from further experimental work. For the past two years or more, Mr. D. H. Browne and his associates have, using the cleaner Eastern coals, achieved excellent results at Sudbury, and for the past year Mr. E. P. Mathewson and his staff at Anaconda have been applying the method with most satisfactory results. Contrary to fears entertained, the ash not only does not blanket the charge, but it is not even necessary to skim. Neither does the dust accumulate in the flues of the waste-heat boilers, it being all caught easily and simply in the chamber at the boiler head. The furnaces work with delightful smoothness and regularity, so much so that a large furnace to handle 700 tons per day is being built, and it is evident that the reverberatory is to make a still further inroad on the field of the shaft furnace. The better results, as compared with those achieved by the pioneers of ten years ago, are not due solely to the use of cleaner coal. A most important factor has been improvement in the art of coal dust firing; mainly in the finer grinding of the coal and its careful drying before being blown into the furnace. Further applications of the process are to be anticipated.

COPPER EXPORTS

Every copper metallurgist, as well as most other people, is aware that of the 1,615,000,000 pounds of copper produced in this country last year, 926,000,000 pounds, or nearly 60 per cent, was exported, chiefly to the countries of Europe. The amounts taken by the various countries in 10 months of 1913 and 1914 was as follows in pounds:

To	1914.	1913.
England	155,962,240	104,944,000
France	112,712,320	122,449,600
Germany	198,132,480	275,963,520
Holland	131,969,600	144,506,880
Belgium	6,442,240	4,941,440
Austria	30,932,160	31,050,880
Italy	43,480,640	35,562,240
Miscellaneous	21,911,280	2,755,200
Total	701,542,960	722,173,760

It is thus seen that Germany was our largest customer, in spite of the fact that it has a domestic output of about 45,000,000 pounds. Germany is a great manufacturing country, and from refined copper makes a large variety of products which not only supply her own domestic needs, but are the basis of a large trade with other countries. The outbreak of the war in August violently disrupted the economic mechanism which had been created out of this international traffic in copper. For a while shipments were completely cut off, as banking and shipping were brought to a standstill. Gradually the currents of trade began to flow again, but shipments to Germany and Austria were permanently stopped, making a tremendous decrease in foreign buying. Domestic buying was much depressed through the uncertainty of the business outlook, and the result was a tremendous increase in stocks of the metal, which for a time threatened to cause a collapse of the copper market. Prompt and united action was taken by the principal producers and sellers of copper, and production was decreased to one-half of normal. Sales to the smaller European countries not at war soon began to increase. This is explained by some on the ground that these countries, which in normal times find it more profitable to buy their manufactures of copper from Germany, were utilizing the opportunity to develop their own manufacturing industry, a view in which there seems a certain amount of reasonableness.

To this, however, the government of Great Britain did not subscribe, taking the view that the increase over the normal takings of copper of these countries was surreptitiously finding its way to Germany. As a result, up to date, some fifteen steamships carrying copper consigned to the smaller European companies have been stopped by British cruisers. In some cases their cargoes of copper have been diverted to England and there paid for at the rate prevailing in England, but considerably less than the rate in the country to which originally consigned. In other cases the copper has been seized and held to await the action of a prize court to determine

whether it is contraband of war destined to supply the enemy. The ground on which these seizures were made was that the copper was not consigned to a well known firm in the country of destination, but was consigned to order at the foreign port, and hence its real destination was indeterminate. The reply of the copper sellers to this is that it is their usual custom to consign copper to their agents abroad, and that when the metal arrives at the foreign port the documents are passed through the banks and the transaction completed. In reply to an inquiry as to what shipping arrangements would be satisfactory, the shippers here were informed that the metal must be consigned to a known firm in the country of destination and a guarantee must be given that the copper would not be resold to Germany. To the first of these conditions the sellers at once acceded, but raised the point that they had no control over foreign firms and could not guarantee what disposal they would make of copper sold to them. The aid of the Department of State was sought, and it at once took vigorous action. As a result, assurances were received from the governments of Italy, Denmark, Norway, Sweden, and Holland that shipments of copper bought in America would not be permitted to pass their borders into Germany and Austria. The government of Great Britain has stated that it considers these assurances satisfactory. Nevertheless cargoes of copper consigned to these countries are still being detained and shipments have been brought to a standstill, since none of the marine insurance companies are willing to insure the copper, nor will any except the few American steamers available receive it as freight. Practically, therefore, nothing has been accomplished to permit shipments, though theoretically the conditions have been met. Fresh representations are being made to the State Department, which is now doing all it can to meet the needs of the copper industry.

NEEDED: CONSTRUCTIVE CO-OPERATION OF MINING MEN

On another page, Mr. H. A. E. Chandler, professor of economics in the University of Arizona, and a gentleman deeply interested in problems of taxation, calls attention to a serious situation. If there exists a sufficient reason why the mining interests of this country should not yield several more millions of dollars for purposes of taxation than they are now contributing to the various state governments, that reason should be clearly set forth by the mining men of America. One thing is sure: there is a general feeling in many states that the mining industry is paying far below its fair share of the expenses of government; and another thing that is almost as sure is that many tax officials are determined to increase the amount of taxes paid by the mining industry as rapidly as means can be found.

In this regard, the mining men may take any one of three positions. They may assume an attitude of indifference, and let come what may. This would be the height of folly, for with the constantly increasing cost of government resulting in constantly increasing pressure upon tax officials for more revenue, the officials are going to do what any other human beings would do under the same pressing conditions—they are going to get the revenue where it is easiest to get it—and the easiest place to get it is in the camp of the indifferent. Secondly, they may assume an attitude of defiance against all increases whenever and wherever they may be suggested, irrespective of the reasonableness of such increases. From a purely selfish point of view, this policy has undoubtedly been successful in some states in the past, because of the preponderance of the influence of the mining interests in legislative matters. Today, however, there are few states, if any, where the mining interests can effectively control public opinion or legislation. With the rising agricultural, commercial, and financial interests all alert to the increasing burdens of taxation, the success of this second policy cannot be expected by any mining man who is sensible to the tendencies of the times.

The mining men of America should learn a profound lesson from the history of railroad transportation in the United States. Few men who are carefully informed upon railroad matters believe that the railroads of the country are getting a square deal from the public at the present time. However, whatever reaction has set in against the railroads is to be traced to the mistaken attitude which the railroads took for many years in regard to public interests. And wherever the almost relentless antagonism of the public against the railroads has been mitigated, this has been the result of a strong effort on the part of many railroads to do whatever the public welfare demanded. Constructive proposals from the railroad men, backed by a willingness to co-operate upon any fair basis, have been responsible for modifying the unkindly attitude of the public toward the railroads; and most of the great transportation systems have come to see that this is the only basis upon which they can expect a 'square deal.'

This suggests the third course that the mining men have open to them in the present matter of the taxation of mines, and it is the only method that can be expected to result satisfactorily to the mining companies.

Men familiar with the work and personnel of the tax assessors of America believe that they would welcome constructive suggestions from the mining men. Of all the problems that confront the tax officials in many states, the question of the equitable taxation of mines is the most perplexing. In vain have the tax officials asked for such suggestions. Many mining men have given some thought to this question, but most of them have looked at it from a narrow point of view; and while their suggestions were mostly of a negative or critical character, the positive suggestions that were made displayed evidence of but a narrow study of the question. Exceptions to this statement must be made; these, however, are rare. The great difficulty from the mining operators' point of view has been that most well informed mining men have been too busy attend-

ing to business to give the matter the attention that it deserved. Out of this difficulty has grown much confusion.

Mining men seem to be almost hopelessly divided upon the subject of taxation. Definite inquiries concerning the fairness of specific methods of taxation bring in most conflicting replies. Not only do the various mining men in the same state differ widely in their opinions as to the same law, but surprisingly different opinions are held by different officers of the same mining company. As the result of an inquiry as to the fairness of a present law addressed to one of the great mining corporations of America, the reply was received from one of the officers of the company that the law was fair and equitable, while another officer of the same company expressed the opinion that "a more unfair law could not possibly have been devised by the brain of man."

While conflicting replies, such as the above, are of considerable interest to the investigator, obviously they do not aid materially in working out a constructive and fair program for mine taxation. If the mining men are to exercise any considerable influence upon the tax legislation of the near future, it is necessary that they should get together and concertedly offer a constructive program to the tax authorities. In this regard, three points stand out with unmistakable clearness:

1. The old time method of obtaining fairness or favor in the matter of taxation by sending a few clever attorneys to the legislature during the session is obsolete. The legislation of the present time is more and more the result of careful study by experts, and especially is this true in present tax legislation. It may be possible for the mining interests temporarily to defeat a revenue bill, but nothing but a constructive program worked out upon sound principles with due regard to other kinds of property will receive permanent sanction from the legislatures.

2. Some well meaning tax officials fail to grasp the important differences which characterize the mining industry as compared with other industries, and these differences should be clearly set forth by mining representatives whose general fairness of mind and spirit of co-operation insure the confidence of the tax officials.

3. If the mining men of the country assume any attitude other than that of constructive co-operation, they will have great difficulty in stemming the tide of opinion that mines should be taxed for a much larger amount than they now bear.

The good effect of co-operative work based upon even incomplete studies of the matter has already been shown by the experiences of the mining men in Nevada and Arizona. In each case strong and representative committees, taking the subject up with the proper officials in a public way, were able to affect materially programs of taxation. In both cases, however, the work was of the emergency order, and the truth seems to be that few mining men have any real knowledge of taxation. The American Mining Congress is about to meet at Phoenix, Arizona. It will be attended by representative men from many states, and particularly by several that took important part in the taxation conferences in Arizona last year. It could not do a more useful thing than to discuss, as fully as the program will permit, the subject of mine taxation and to follow the discussion by the appointment of the strongest possible committee charged with the duty of studying the matter and conferring with the tax officials of the various states, especially at their meeting at San Francisco in September 1915. The needful thing is first to clear up our own ideas as to taxation and then present a united, tactful front to tax officials.

BUCKING VERSUS BACKING NATURE

One of the greatest mistakes which can be made in planning any enterprise is consciously or unconsciously to oppose the forces of nature, for these forces are never-ceasing in their action, and must be met with an equally relentless and correspondingly expensive opposition. If a building is so situated that the surface water drains into its basement, a pump must be kept working to lift it out again. If a building is so situated that the snow drifts about it, much labor must be expended each winter in keeping paths to it open. If the building is so placed that it encounters the full force of the winter winds and does not get the benefit of the sun, many extra tons of coal must be burned each year in order to maintain the interior at working temperature. There are many less obvious cases. Heated gases tend to rise, and if in the flues or other passages of a furnace system they are made to travel downward it is only done at an expenditure of energy which is not visibly reflected in the cost sheet, but is there, nevertheless. A body in motion or at rest tends to continue in that state; to start a body at rest or to stop a body in motion requires a considerable expenditure of energy. If the material in transit through a milling plant is continually being accelerated and retarded, the power plant is furnishing the energy thus consumed. Just because the bookkeeping department does not isolate it as a separate cost does not alter the fact that it appears somewhere in the total. A laborer expends only an average amount of energy in a day's work; if he works in a cold place part of it is expended in keeping himself warm. If he works in a hot place, an equal or greater amount is expended in keeping himself cool; if he has to work in the dark, energy is expended in trying to see; if he has to work in a dangerous place, nervous energy is expended in trying to guard against the dangers. Doors that open the opposite way from that naturally expected, bolts and nuts that screw to the left instead of the right, steps up or down in unexpected places are all "little foxes that steal the grapes" of efficiency. The man who designs his plant so that the forces of nature work with him, has the cheapest and best colaborers; but the man who designs his plant in opposition to natural forces, must pay the cost every operating day.

ARGO TUNNEL AND MILL, IDAHO SPRINGS, COLORADO.

Cyanidation of Clear Creek and Gilpin County Sulphides

By JACKSON A. PEARCE

Clear Creek and Gilpin counties, about 30 miles from Denver on the eastern slope of the Rocky Mountains, embrace a heavily mineralized region which has been continuously mined for the unusual period of 55 years. The first few years of this period were devoted to placer mining, from which an enormous amount of gold was produced. Following this, attention was devoted to the lodes, whose enriched and oxidized surface orebodies yielded great quantities of gold, and whose sulphide zones yielded gold, silver, and lead. The total production has been large. But the placer gold has long since found its way to the mints, the bonanza lode deposits have been looted and milled or smelted, and little is left today except the low-grade ore deposits, too low to stand transportation and smelting charges, too complex to yield satisfactorily to the standard milling practice of the district. For many years operators and metallurgists have busied themselves with these ores, and one may find here a vast number and a wonderful variety of mills. The mills are strewn along the river banks and up the mountain sides in such profusion as to suggest the visitation of epidemics of mill construction. Great as is the number, they represent only in part the money and effort put forth to treat the complex sulphides of this district. Some have been successful in having recovered enough to pay dividends, but, so I am told, fully one-third of the value of the ore found its way to the rivers.

Since the early days of the old Gilpin County bumping table, concentration has been the standard treatment. Frequently the mills are equipped with some auxiliary process, such as amalgamation, magnetic separation, chlorination, or cyanidation. Notwithstanding the world-wide popularity of cyanidation, it is only recently that the process has made headway on these ores. Although it was tried frequently, cyanidation was not successful. The Hudson cyanide plant, rebuilt in 1912 and in operation for several months, was closed down an apparent failure. The Argo mill, constructed in 1912-13 and equipped with modern machinery, was closed down after an unsuccessful run of seven months. Under new management, however, the Argo has been in successful operation since the first of January 1914. Upon the supposition that the success attending the cyanidation of complex sulphide ores in this remodeled custom mill may be of some interest, a brief description of the plant is here given.

Ore Supply

Almost without exception the orebodies are mineralized feldspathic zones, irregular in shape, extent, and in mineralization. Quartz veins are of rare occurrence. Frequently the interstices of these granular feldspathic dikes are so impregnated with loosely adhering, coarsely crystallized pyrite, or other sulphides, that a mere fracturing of the ore disengages a large part of the sulphide. These ores, as exemplified by those from the Gunnell mine, yield a fair amount of their precious metals to concentration, and this explains the strong hold that concentration has on the district. At other places, as for instance in the Gem mine, silicious cementation has attended the mineralization, and a highly silicified though not a quartz orebody has resulted to which concentration is not so readily adapted. The economic minerals are galena, chalcopyrite, chalcocite, sphalerite, argentite and other silver minerals, and gold. Sylvanite seems widely distributed, though not in abundance. Pyrite and marcasite are everywhere abundant.

The ore supply for the Argo mill comes largely from the Argo (Newhouse) tunnel and its many laterals. The Argo 'tunnel' is a great cross-cut adit more than four miles in length, cutting at a depth of 2000 ft. many of those veins which in the early days of surface exploitation were famous producers. Much of the ore now taken from the adit is unsuitable for direct shipment to the smelting works, and must stand a preliminary local treatment. While the ore supply from the outlying properties is well worth considering, it is neither so large nor so steady as that from the adit.

Sampling

The ore is received at the weighing station in trains of three-ton cars, weighed nine cars at a time, and delivered to a storage bin to await a time for sampling. There are 22 of these individual storage bins with a combined capacity of 1400 tons. They are fitted with an overhead track on which is operated a self-contained traveling revolving tipple, capable of discharging three cars of ore at a time. Beneath the discharge chutes on the lower side of the bins a plate conveyor, running the full length of the bins, serves to convey the ore from the bins to the sampler.

The sampling plant is an institution by itself, having no place in the flow-sheet of the mill, except that in it the coarse crushing is done. It serves only to prepare the samples on which settlements are made for the ores. All ore is purchased outright and is paid for as soon as assays are available. Sampling in this manner adds greatly to the costs of mill operation, but seems to be a necessary evil.

Mill Equipment

The mill proper is equipped with twenty 1000-lb. stamps dropping 114 per minute through 6 in.; one 4 by 10-ft. tube-mill, 33 r.p.m.; Dorr classifiers and dewaterers of various sizes and types; five Dorr thickeners, of 20 and 22 ft. diam.; one Dorr agitator, 20 by 12 ft.; one 8-ft. Portland filter, 6-minute cycle; 10 Card concentrating tables; one 14 by 8-in. Blaisdell air-compressor; zinc-boxes, pumps, and all the usual mill accessories. The mill is motor-driven throughout, back-geared motors being used for the battery drive. A modern steel building encloses the ore-bins, sampler, and mill, with concrete floors throughout.

Mill Flow

Owing to the dual nature of the ore, as noted above, it has been found expedient to adopt a somewhat divided flow-sheet. The mill was originally designed to take advantage of the ease with which the sulphide is separated from the feldspathic gangue. The ore was to undergo moderately coarse crushing, say through 12-mesh, to liberate a high percentage of the mineral content, some of which would be slimed; a concentration of the coarse to remove the liberated minerals; discharge of the barren sand to waste; and cyanidation of the slime. It was found, however, by an expensive mill test that this scheme was not applicable to those ores in which silica was deposited, contemporaneously it seems, with the other minerals. This tough, fine grained silicious cement, chalcedonic in appearance, contains minerals finely disseminated throughout its mass. Coarse crushing does not liberate the minerals, which are consequently carried into the sand discharge.

To prevent this loss the battery bin has been partitioned, and a double flow-sheet adopted. One compartment is reserved for those ores from which a fairly clean separation can be made by coarse crushing; the other for those for which fine grinding is essential to good extraction. For the latter, owing to limited tube-mill capacity, 20-mesh screens are used, while 16-mesh screens are used for the former. At present 10 stamps are provided with 16-mesh, and 10 with 20-mesh. With this screen equipment the capacity of the mill is slightly over 100 tons per day.

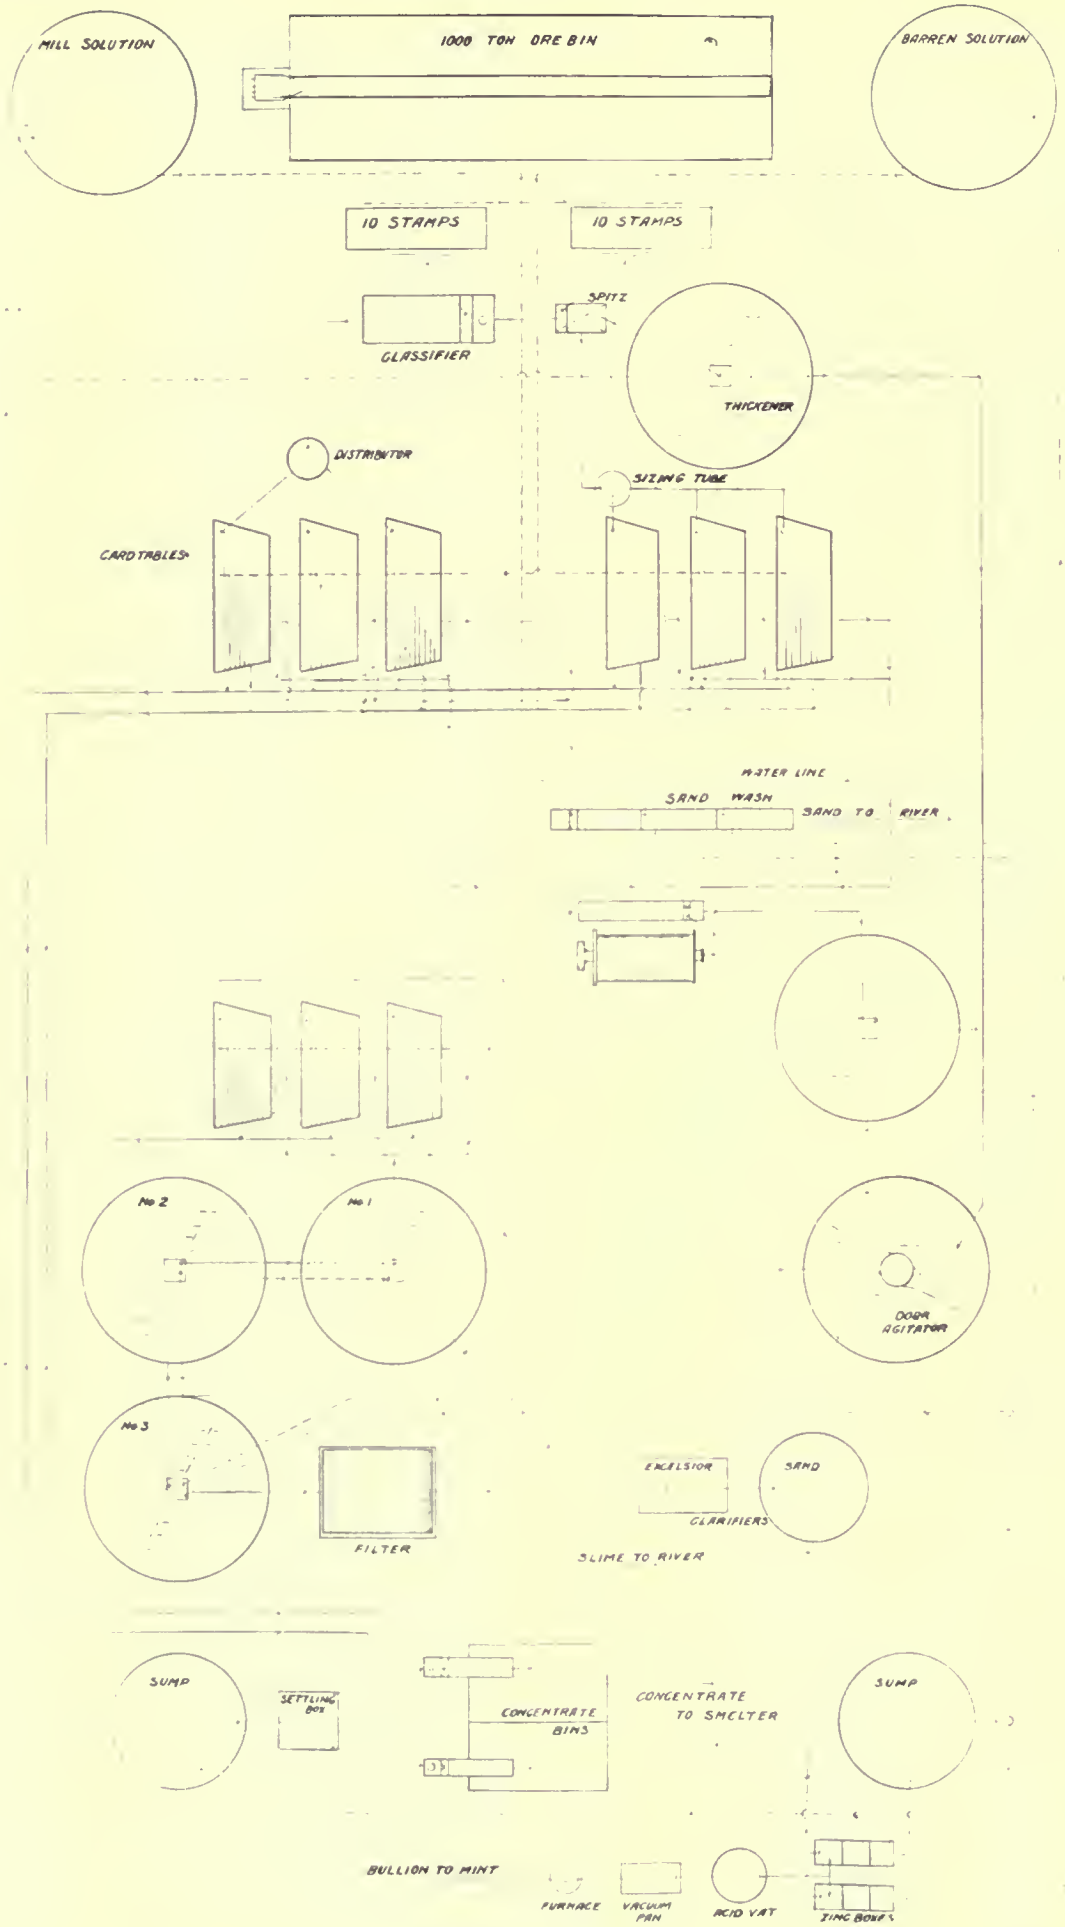
The present practice is to crush in solution. The product from the 16-mesh screens is classified in a Dorr duplex classifier. The sand is concentrated on Card tables yielding the four products, lead concentrate, iron concentrate, middling, and sand.

The Primary Concentrate

A clean iron concentrate is produced on the primary tables, throwing as much pyrite middling to the tube-mill as it will handle. In its course through the tube-mill and agitator a considerable amount of gold is dissolved for which the mill receives $20.67 per ounce from the mint, as against $19 from the smelting company. The difference in price more than covers the differenee in treatment cost. For this reason it is advantageous to get as much gold as possible by cyanidation. On some ores it would pay well to cyanide direct, or to cyanide the concentrate, if the mill equipment permitted. It may be said here, in a general way, that the ores of this district are refractory or complex only in the light of local methods of treatment. Some ores on which laboratory experiments have shown good extractions would be refractory if not actually disastrous to a mill of this or any other local type. These remarks apply more particularly to the gold ores. The silver is not so readily cyanided as that in ores of Tonopah and elsewhere.

The lead and iron from the primary tables go by individual pipe-lines to Dorr dewatering classifiers, being dewatered to 12% moisture, thence to their respective bins near the loading station. The middling goes to a tube-mill in closed circuit with a Dorr classifier. The sand from the primary tables goes to a Dorr three-stage sand classifier for wash.

This efficient, continuous, sand washing contrivance is a series of three classifiers delivering the sand from one to another and finally to waste. In the first stage the sand is dewatered and advanced to the second stage. Here it is washed with barren solution and advanced to the third stage. In this stage it is washed with water and discharged to waste. The sand carries sufficient gold to warrant regrinding, but for the limited tube-mill capacity. The only tube-mill is kept to capacity



FLOW-SHEET, ARGO MILL.

with sand, thus keeping at a minimum the amount of sand discharged.

The slime overflow from the duplex classifier at the batteries joins the product from the 20-mesh screens in a spitzkasten. The underflow is classified and concentrated, yielding lead concentrate, iron concentrate, and a coarse product going to the tube-mill.

Heating the Solutions

The spitzkasten overflow goes through a thickener to the Dorr agitator. The overflow from the tube-mill classifier is also thickened and sent to the Dorr agitator. The success of the mill is largely due to the condition of the agitator charge. Made up, as it is, of the many different ores coming into the mill, it is impossible to manipulate it to the best advantage for each individual ore. A temperature of 90°F. might profitably better the extraction on some ores, especially on silver ores, but with this temperature on other ores, the cyanide consumption is excessive. At this temperature the rate of settling is increased on some ores, but diminished on others. Tests on some ores have shown that a temperature of 90 to 100°F. disengages a gelatinous substance extremely difficult to settle. With some ores, cupriferous ores especially, the cyanide consumption is excessive, if the strength of solution exceeds 1.7 lb. cyanide per ton. A stronger solution would probably increase the silver extraction, but not sufficiently to compensate for the cyanide loss. It has been found the best practice to keep the agitator at 60 to 64°F., with the solution at 1.7 lb. cyanide per ton. Lime is kept at 0.8 lb. per ton, this strength having been found the most effective for settling, and more ample for cyanide protection. The consistence of the charge is kept at 2 to 1.

To maintain the solution at the desired temperature, steam coils and live steam are both used. Heating the solution in the summer time is a matter of ease, but in winter it is the same problem as at other mills in zero weather. To conserve the heat due to surface radiation at the thickeners, a thick layer of foam is allowed to encrust the whole of the surface. An uninterrupted overflow of clear solution is maintained by encircling the foam with No. 16 sheet iron spaced ½ in. from the periphery of the vat and extending a few inches below the foam. To ascertain the condition of the thickener, a drop light is lowered through a small casing in the foam.

From the Dorr agitator the slime is concentrated on slime tables to remove as far as possible those sulphides escaping from the primary tables together with those liberated in the tube-mill circuit. This concentrate is sent to the iron bin. A liberal amount of silica (30 to 40%) is cut in with the iron, the intention being to make a division at that point where the assay value of the mineral-bearing silica equals the marketing costs on the concentrate. A penalty on silica of 10c. per unit on all over 15% is avoided by properly mixing this concentrate with that low in silica from the primary tables.

After concentration, the slime goes to the first of a series of three Dorr thickeners to be washed by the counter-current system. In this system the solution advances from 3 to 2 to 1 by gravity, while the pulp is advanced from 1 to 2 to 3 by means of diaphragm pumps. Diaphragm pumps are excellent for forwarding pulp. On some ores the pump will deliver pulp at 33% moisture. Freshly made diaphragms last about 10 weeks, but those from stock puncture within 10 or 12 days. The wash for the third thickener is a mixture of barren solution and the wash water from the third stage of the sand wash.

From the third thickener the pulp at about 1½ to 1 is sent to the Portland filter, where the cyanide solution with a small amount of dissolved gold is displaced in the cake by sprays of water. The cake is then discharged to waste.

Filtration Introduced

The mill was designed to operate without a filter. This system of treatment probably was decided upon without an adequate knowledge of the character of the ores to be treated. Many of the ores for which the mill was designed have low settling rates, rendering continuous decantation without filtration impracticable. At times ores are received of such low rates of settling that with half the normal thickener feed the overflow is muddy while the underflow is carrying 50% moisture.

Solution for precipitation is taken from the overflow of the first thickener after agitation, or from either thickener before agitation. It is clarified by upward percolation through a vat of excelsior, followed by a sand filter, and precipitated on zinc shavings. Two boxes, each of three compartments, handle the 200 tons of solution precipitated daily. Each compartment is 30 in. on a side and charged with zinc at the rate of 10 lb. per cubic foot. Little difficulty is experienced in precipitation, provided the solution is properly clarified.

The boxes are cleaned up twice a month, the product acid treated, dried, and melted in a Donaldson tilting furnace. Copper in the precipitate, unless especially treated, gives an undesirable matte and a poor grade of bullion.

Besides the sampling plant the mill maintains an exceptionally well appointed assay office. With a two-muffle low-pressure fuel-oil furnace, one assayer completes from 50 to 75 assays per day. The most interesting feature of the office is the monolithic, reinforced concrete, balance stand designed by O. F. Heizer, the manager. It was designed to overcome vibrations due to passing trains, and although trains pass within a few yards of the office, no vibratory effect is produced.

It will be noticed that no effort is being made to save zinc or copper. Although both are of value, this mill is not equipped to save them. The zinc is buried in the iron to escape penalty, while the copper is lost in the slime and in the iron.

A small amount of lead is recovered, which is valued no more for the amount received for the lead itself than for the reduction in working costs it insures at the refinery. The maximum price paid for gold by the smelt-

ing company is $20 per ounce, and this is on condition that the concentrate contains 5 oz. or more of gold per ton. Unless it is a lead concentrate (5% lead or more), the working costs are excessive. Cutting enough iron into the lead to bring the gold content down to 5 oz., the lead still remains above 5%. In this manner, although a small loss is suffered in the price of lead, due to the lower lead content, a substantial gain is made in getting a maximum price for a maximum quantity of gold with a minimum treatment charge.

The ores treated at the mill are valued principally for the gold and silver. Of the combined content of these two metals, slightly over 90% is saved. A 90% extraction may not seem a high standard of mill practice, but it should be remembered that this is a custom mill, and that metallurgically and financially there is a considerable difference between a custom mill and a mine mill. Generally speaking, a mill operating for the benefit of a mine is assured a constant supply of ore. Whether the supply is great or small, it is dependable, and plans are laid accordingly. With a custom mill, especially with one in competition with other mills as well as smelters, the supply is not so dependable. When the supply is not sufficient to keep the mill running to capacity the overhead, labor, and power costs per ton rise quickly. If the mill be closed down pending the accumulation of ore, the mill crew scatters, the shippers, unable to get timely settlements, dispose of their ores elsewhere, and trade is lost.

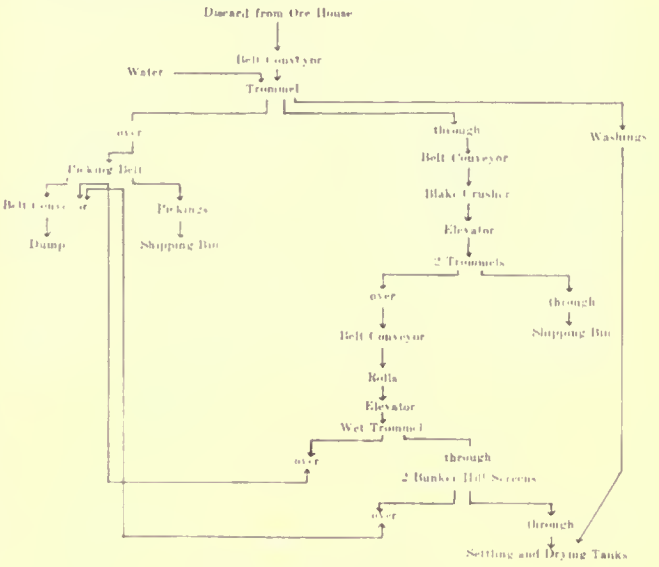
The mill at the mine, as a rule has ore of a definite character to treat, even though it may be a difficult one. The mill may be constructed or altered to the best advantage for that ore. It then becomes a pleasant and encouraging occupation to better the extraction, or to reduce the working costs, even to a slight extent, knowing the results will be continuous. With a custom mill, especially with one within a district in which ores of so many different characters are found, the treatment is much more difficult.

There is also a difference in the margin of profit. According to the schedule of treatment charges of the Argo mill, an ore assaying $15 per ton calls for a $5.50 treatment charge. This $5.50 corresponds to the mill head in a mine mill. It covers the cost of operation, maintenance, depreciation, and insurance, as well as mill loss and profit, as would be true of a $5.50 ore at a mine mill. However, viewing both in the light of percentage extraction, this difference may be noted. A 90% extraction on a $15 ore ($5.50 mill head for a custom mill) is a loss of $1.50 in the tailing. This loss on the $5.50 mill head of the mine mill represents an extraction of only 73%. Or, a 90% extraction on each ore means a loss of $1.50 on the one, but only 55 cents on the other—the appreciable difference of 95 cents per ton. Of course, the mine mill is also expected to pay for the mine and the mining of the ore. This is largely balanced in the custom mill by the extra cost of sampling, resampling, of controls and umpires, and other added expenses of purchasing ores.

The Vindicator Mill

By HORACE F. LUNT

The common method of handling ore in the Cripple Creek district is to dump it from the mine cars over screens of from ½-in. to 1½-in. mesh, and to hand-sort all that passes over the screens. The screenings are usually a shipping product. In some parts of the district the gold is found mainly in the coarse rock; in others, in the fine. The latter is the case at the Vindicator. In order to save that part of the gold which is ordinarily lost in the rock discarded by the ore sorters, the Vindicator company, which is one of the largest producers of the district, after considerable preliminary experimenting, is just completing a plant for the treatment of this material. The mill is a washing and sorting plant, rather than a concentrator in the ordinary sense of that term. Plants of a similar kind have already been built at neighboring mines, but none of them are so complete as this.



FLOW-SHEET, VINDICATOR MILL.

In the Vindicator ore house all the ore from the mine is broken by hand to pass screens having 6-in. square holes, and goes thence over the regular screens, the oversize going to the sorting tables and the screenings to shipping bins, as in nearly all Cripple Creek ore houses. The rock discarded by the ore sorters, instead of going directly to the dump as is the common practice, is thrown on a belt-conveyor and carried to the new mill which adjoins the ore house. This belt-conveyor discharges into a trommel having 2-in. round holes, where the rock is washed by sprays and all the fine dust removed from it. The oversize goes to a picking belt, from which the first shipping product is obtained. The picking belt discharges upon a belt-conveyor, which in turn discharges on the dump. The undersize from the trommel is carried by belt-conveyor to a Blake crusher, the product of which is elevated to two trommels, from which the undersize goes to shipping bins and the oversize to rolls for further crushing. The product of the

rolls is elevated to a wet trommel, from which the undersize goes to two Bunker Hill screens and the oversize to the belt-conveyor to the dump. The undersize from these screens, together with the washings from the first trommel, goes to settling and drying tanks from which another shipping product is obtained; the oversize goes to the dump.

The building is of structural steel, covered with galvanized iron over asbestos board. It is unusually roomy and well lighted. The machinery is driven by individual electric motors. The shipping bins discharge directly into railroad cars. The plant has a nominal capacity of 300 tons per day, but it is not expected that it will be run at full capacity for some time.

Mine Taxation and the Conference of Tax Officials

By H. A. E. CHANDLER

The taxation of mines in the United States was chosen as one of the principal topics to be given important place in the annual conference of tax officials that was held in the Brown Palace hotel, Denver, Colorado, in September. In view of recent increased interest in mine taxation, as well as the convenient situation of the meeting place, it had been expected that the mining men especially of the West would attend in considerable numbers. The one surprising thing about the conference, however, was the almost total absence of mining men or their representatives. Here in the very centre of the mining territory were assembled those who levy upon the mining industry millions in taxes every year, and who, from repeated expressions, give the impression that they intend to impose still higher taxes upon the mines as soon as means to that end can be found. The best opportunity that the mining men have ever had to meet the tax experts and the tax commissioners of the United States, and to present the case for the mining industry, was offered at Denver. Yet this opportunity, the like of which seldom occurs under such favorable circumstances, was apparently totally ignored.

The mining industry is the one great industry that needed representation most, and yet it was almost the only one which was not represented. The other important industries of the country, including the transportation systems, the telephone and telegraph systems, the express companies, Wall Street and the money interests, and public service corporations, were all represented. These have learned that the surest way to obtain a square deal in the matter of taxation is to meet, upon the cordial basis offered by the tax conference, those tax experts and public officials who exercise such a large influence in forming and administering present tax systems.

A great gulf, seemingly unbridgable, in the matter of taxation exists between the mining men and the tax men. The mining men of Arizona, Colorado, California, West Virginia, and other great states in the East and West feel strongly that they are overtaxed. The tax commissioners of many states, on the other hand, believe that the mining industry had never paid and is not now paying its just proportion of taxes. At the present time this statement may not apply to Michigan, Minnesota, and Wisconsin, but it does apply to many other states.

Without conferences between the officials and the mining men, how can this ever-widening gulf be bridged? If the mining men were in the majority in the several states, or even in a large minority, they might hope to control the policy of the states in regard to the taxation of mineral land. The ever-increasing influence of the agrarian party, plus the increasing influence of conservative representatives of the transportation, industrial, and other financial interests, prevent the shifting of the growing tax burdens from the mining men.

In the United States there exists today one body of men that is coming to exercise an almost preponderating influence in shaping the fiscal policies of many of the progressive states, and that is the National Tax Association. The influence of this organization has grown so rapidly that it now includes most of the principal tax authorities and tax experts as well as many of the tax commissioners and members of the boards of equalization. Among its members are many of those who have been largely responsible for the creation of tax commissions as well as for much of the tax legislation that has been enacted in the past ten years. At the annual conferences the mining interests ought to be represented by some of their ablest talent. And so long as the mining operators continue to fail in doing this they must not be surprised when their taxes go skyward.

Publicists and financial experts foresee no hope of any substantial reduction in taxes. In fact, all reliable indications seem to point to a continued increase in the cost of government, both federal and state. To meet this growing demand for more revenue, tax officials are now racking their brains. It is only reasonable that the state officials should look to the mining interests for part of this increase; and to the end that this increase should not be disproportionate, the mining interests should be prepared to argue their case when it again comes before the great tax court of North America—the annual meeting of the National Tax Association.

The next annual conference will probably be held in San Francisco, September 1915. At this conference the committee on the taxation of mines will give in its report, the results of three years' investigation. The conclusions of this report will undoubtedly have considerable weight with the delegates to that conference, and also exercise influence upon subsequent tax legislation pertaining to mines.

Application of Jigs to Gold Dredging

By J. W. NEIL

During the summer of 1912, the Yosemite Dredging & Mining Co., operating a 3½-cu. ft. close-connected bucket dredge on the Merced river, made a series of tests to determine what gold, if any, was being lost. These tests were made by securing samples from the fine material passing over the tables and also by driving pipes through the 'fines' to bedrock at close intervals across the pond. These various samples were sent to the laboratory of the General Engineering Co. at Salt Lake City, and the tests were made there on machines of working size. These tests revealed the presence of from eight to ten pounds of black sand per yard of gravel dug, and that this black sand was a 'detainer' and not a 'container' of the gold. These tests further checked closely the difference between the values shown by the drill and the actual recovery, and showed the fine tailing to carry about three-quarters as much per cubic yard as the recovery showed per yard dug; that is, say the drill value is 12½c. and the saving 10c. (or approximately 80%), leaving 2½c. loss per yard dug. This, contained in the 'fine,' which is only one-third of the gravel, would make this run 7½c., and such values were usually found. The gold is for the most part free and recoverable by concentration and amalgamation.

In view of the apparent losses as shown by these tests, it was decided to attempt further recovery, and to this end a small jig equipment was planned, and, in the fall of 1912, placed on the dredge. This dredge was equipped with a shaking-screen, distributers of old type, eight tables with riffles on each side, discharging into one side sluice inside the boat. The total riffle area, including the side sluice, was 980 sq. ft. The distribution was always poor, too much of the fine material being delivered on the first two tables on each side. The records of many clean-ups showed that 90 to 92% of the gold was taken from the upper four tables on each side. Otherwise, conditions were excellent for gold saving, the gravel being a clean river wash, containing no clay and such top soil as existed being a light sandy loam which did not foul the water.

The first jig placed on the dredge was only 4 in. wide

by 30 in. long, and the pulsations were first obtained by water pressure by means of a rotating cock on the Richards' system. The jig was placed in the side sluice just below the discharge of the fourth table; thus it had to handle all the fine material from four tables, representing the losses from 90% of the output of the dredge. This first jig did not have pulsations strong enough to keep the bed free. When sufficient water was admitted to keep it free, there was so much of it that the object was not attained, as the upward flow was so strong that it carried away all of the light gold and the concentrate made did not show any value. The jig was therefore altered, placing an ordinary plunger in the water compartment and running by eccentrics about 180 r.p.m. With this jig, concentrate was made at will, either quite clean black sand or half and half, according to stroke, under-water supply, etc. With this jig about two tons of concentrate was made on which to make further tests. Average samples of these concentrates were sent to the Salt Lake firm and exhaustive tests were made to prove the metallurgy of the concentrates, and of tailing from the jig and from the pond. These tests demonstrated satisfactorily that by using ordinary amalgamated copper plates with a Pierce amalgamator following, over 95% of the gold could be saved.

The average value of the concentrate shipped was $15.58 per ton in gold, but to our surprise it contained no platinum. Eight pounds of concentrate per yard on 3000 yd. at $15.58 per ton looked like an asset, and although all of the black sand was not expected to run

as well as this small amount saved, still it looked like a good venture, and eight large jigs were ordered. These were of the Woodbury type with plunger compartment in line with the flow of the material, ahead of the screen compartment, so that the materials in the sluice passed over the covered plunger compartment. Each screen was 12 by 28 in., the plunger the same, and the stroke made variable by adjusting the eccentrics, which were of the Evans type, giving a true vertical motion.

These eight jigs were placed at the ends of the first four tables on either side, the tailing being dis-

charged into the side sluices as before. The concentrate made was discharged through plugs in the hutch. This was caught in the launders leading to a cross-conveying launder, which discharged into the suction of a 2-in. centrifugal pump. This pump elevated the material to the upper deck into a pointed settling box, from which the concentrate was drawn off and run over 24 sq. ft. of amalgamated plates. The concentrate, after passing over the plates, was run through a small Pierce amalgamator and the discharge from this emptied into the pond. An outline of the arrangement is shown in the illustration on page 840.

Bedding the Jigs

No granulated cast iron for the bedding of the jigs being available, they were finally started with a bed of steel punchings mixed with lead shot. This made a lot of trouble, and consequently the adjustments were necessarily very slow, as stoppage of a jig was not allowed to interfere with the running of the dredge, and only at oiling time, or when it was necessary to stop the dredge for other purposes, could any adjustments be made to the jigs. Thus it took a long time to get the apparatus in good working order. Troubles arose mostly from screens breaking or from loose bolts on the plunger rods, etc. I think it would be safe to say that the entire eight jigs did not run, as a unit, over 50% of the time.

For three months, experiments were made with burlap, canvas, etc., instead of amalgamated copper plates, but it was found that these materials did not work well at all, and the net saving of these three months was only about $12.50 total. During the year of experimental work the entire saving amounted to $1764.12, which was estimated to have been derived from approximately one-half the yardage, or 448,000 yd., representing a saving of 0.38c. per yard of gravel jigged. The upkeep costs during the year totaled $376. Numerous tests made during this period showed that the jigs were delivering about 12,000 to 15,000 lb. of sand over the plates. This concentrate was about 25% black sand. Therefore, it was plain that only about 25% of the black sand, as shown in the preliminary tests, was being saved by the jigs, and further tests on the tailing behind the boat showed no appreciable diminution in value.

It was decided to build a new dredge on another piece of ground, and, desiring to give the jigs more screen area on this new boat, but at the same time to avoid the nuisance of overhead pulleys and shafting, search was made for some more suitable type of jig. Not finding one suitable for the requirements, I worked out a design to suit our special conditions. This new jig, instead of having a plunger operating in a separate compartment, has both compartments alike fitted with screens, and the pulsations are produced by the oscillations of a paddle which hangs from a shaft placed between the two screens and is rocked back and forth by means of a lever which projects through the partition between the screens, and is there attached to and operated by an eccentric on a conveniently located shaft. A line sketch of this scheme in its simplest form is shown in the cut on page 840, also a cut of the old style Woodbury type jig for comparison. The pulsations of this type of jig are positive, and may be adjusted by change of stroke. The screen area is practically doubled, and the jig fits into the usual dredge sluice, as shown in the cuts of the arrangement on the Yosemite No. 2 dredge. The jig frame or box is made of a single iron casting, as are the paddles. The screens are now made of Monel metal, specially woven for this use. This material gives excellent satisfaction, neither rusting nor amalgamating, and does not blind at all.

The new dredge has been equipped with ten of these jigs, set at the lower ends of the first five tables on each side and operated by eccentrics running on shafts

at the side of the boat. These are driven by special motors on the upper floor. There is one centrifugal pump for each side, and also separate settling-boxes and double sets of amalgamated plates, 96 sq. ft. in all. When these jigs are in operation, tests have shown from 25,000 to 30,000 lb. of sand per day passing over the plates, and a sample of this sand taken during the several shifts at regular intervals of 15 minutes showed a content of 22.8% of black sand, 63% of which is magnetic. A sample taken during this same period from the tailing material passing off from the two uppermost jigs, showed only 0.23% black sand, thus showing a ratio of concentration of 100 to 1. Even this comparison is not quite fair to the jigs, as the sample of jig tailing was taken from the two jigs which carry the most sand, while the tailing from the plates came from all ten jigs. The tailing from the lower three jigs does not show any black sand at all.

It is too early to speak of recoveries in this new plant. They will not be as large as the old one, as the gold in this ground is coarser, and consequently does not travel. There is also a much improved system of distribution, so that the upper sluices receive their proportion of sand and water. It must be understood that unusually good conditions obtain here on the Merced river; that is, no clay, a clean wash, the water is relatively clear, and the gold is clean and easily amalgamated. In other localities, where the gold is fine, rusty, or greasy, or where the distribution is not good, such a jigging plant will undoubtedly greatly improve the saving, and is certainly a splendid insurance against losses. Naturally, in cases where the black sand contains the gold, or in tin dredging where all of the value is in the concentrate, this system would afford relief from the need of constant clean-ups and should also greatly improve the recovery.

Application to Tin Dredging

In the case of tin dredging, it would undoubtedly be wise to place several jigs in sequence, so that the failure of any one jig or screen would not cause loss of metal; in other words, a tin dredge of this type would be a floating concentrator, fed by digging buckets, screening its product more perfectly, and possibly to two or several sizes as required, jigging the screened sands and delivering the jig products to Wilfley tables or other tables for final clean-up; or the usual sluice could be installed with riffles, say through the first 40 or 50 ft., and then the jigs set to save the fine product; the riffles or other methods being used to catch the heavier concentrate and the jigs being relied upon to make the final recovery of fine mineral. Either one of these methods would undoubtedly greatly improve the recovery on tin dredges and with a great reduction in the amount of manual labor required.

On gold dredges, where greasy or rusty gold is present in considerable amount, it would be necessary to follow the jigs with table work, so as to get a concentrate of sufficiently high value to make its treatment easy. In this way we produced a concentrate, using the Wilfley table, assaying 44 oz. of gold per ton and representing a concentration ratio of 899 into 1. I specifically mention the Wilfley type, as with this table it is possible to divide the product, making a concentrate, middling, and tailing, and in this way to make cleaner tailing. In our tests on sands from the Merced river, the pure black sand carrying 69.4% iron assayed only 12 to 16c. per ton, and I have had similar results from black sands from other sources, so that I am of the belief, as already stated, that in most cases the black sand will be found to be only a 'detainer' of the gold, but in that rôle may be used as a collector of the precious metal, as copper or lead is used in smelting operations.

As to the cost of the operation of these jigs, they should require no special attendant, the regular dredge crew taking care of the oiling, etc., and the dredgemaster giving whatever other attention is required. As previously stated, we have never stopped the dredge on account of the jigs, any repairing that was necessary was so done when the dredge was shut down for other purposes.

Power Requirements

The actual power required for each jig is less than ½ hp., and the total motors used in operating the 10 jigs we now have in use is 16 hp. This includes underwater supply and sand pumps for elevating the concentrate. On a dredge where the tables are sufficiently high above the deck, this sand pump would not be necessary, as the material could be passed directly over the plates and into the pond. The jigs themselves are of sturdy construction, and the first cost is not great. They may readily be set in a space cut in the table on any running dredge and the products taken care of as conditions demand. Our experience is such as to lead us to believe that recovery on most dredges now operating can be improved by this method.

The Homestake mine, Lead, South Dakota, in four years and seven months, from June 1, 1909, to December 31, 1913, produced 6,663,585 tons of ore yielding $26,138,962, an average of $3.912 per ton. Dividends paid during this time amounted to $6,514,242. During four months of the period the property was idle on account of labor troubles, both production and dividends being suspended.

The South American Copper Syndicate realized $305,000 from ore produced during the year ended June 30, 1914. The net profit was $49,000. A dividend of 75%, equal to $43,000, was paid last December. Smelting operations were handicapped by numerous difficulties. Work was suspended on account of the war.

Gold output of the Raub mine, Federated Malay States, was $19,000 from 7881 tons of ore during the four weeks ended September 12.

Metal production of Broken Hill in July was valued at £440,360, and in September, £150,806, a large decrease due to the war.

Machine Drilling Efficiency

By THOMAS M. BAINS, Jr.

During recent years there has been an increase in drilling speed and improved efficiency, which has principally been due to the improvements in machine drills, better ventilation, and improved facilities for removing broken rock from the face. There is one other factor, to which little attention has been paid by mine operators, and on which speed and efficiency of rock drilling depends to a great extent. This article is written with the idea of calling attention to this other step toward greater speed and efficiency.

Factors in Efficiency

The factors that control the speed of machine drilling may be classed under the following heads: (1) geological, (2) human, (3) mechanical devices, and (4) drill steel. The geological factor covers the character and structure of the rock, the underground water conditions, emanations of gases, etc. In most cases these have to be taken as they occur. The second factor, the human equation, deals with the men running the machines and the bosses over them, and is one of the variables in the drilling equation that may be improved only by securing better and more skilled men. The third factor has had great thought bestowed upon it by both mine operators and manufacturers. The mechanical devices for drilling, ventilation, 'mucking,' handling water, etc., have been perfected along many lines. The result today is high mechanical efficiency in these lines. The recent bulletin of the Bureau of Mines on 'Safety and Efficiency in Mine Tunneling' covers this ground thoroughly, but the fourth factor, that of drill steel, is not mentioned except in connection with drill-sharpening machines.

Sufficient attention has not been paid to the fourth factor. With adequate steel, properly sharpened and heat treated, a machine man can drill twice the depth of hole that the same man under similar conditions can with too few drills or with plenty of steel which has been subjected to improper heat treatment. The process of sharpening and gaging has been worked out mechanically, by means of drill-sharpening machines.

Sufficient Steel at Each Working Face

The purchase of sufficient steel and turning it over to the blacksmith does not mean that sufficient steel will be at each working face. In cases where contractors and company men work in the same mine, the contractors will 'corner' the steel and the company men will be short. Few mines in this country seem able to get steel to the machine men so that they will have a sufficient supply. It is generally left for each 'shifter' to secure steel for his shift or else each individual must 'rustle' his own steel.

In one of the largest of the Eastern mines, the steel was lowered down the shaft to the station once each shift. The machine men or helpers waited for it like a pack of wolves. Before the cage was within two feet of the level of the station, a rush like a football scrimmage took place. Men with seven or eight 'starters' would exultantly dash away from the cage, while others secured all long drills. Some would not secure any at all. In one case, two men had a four-foot and two six-foot drills with which to drill a complete round.

The same conditions hold in Western states. A case similar to the above occurred in one of the large Mother Lode mines of California. The company operating the mine had from 100 to 200 men on its payroll. The mine finally shut down, having a deficit of $90,000 for the year. The company then leased the different levels to some miners who had previously worked for it. Thirty-four lessees produced nearly the tonnage that the average 150 company men had. The mine finally closed down when the shaft swelled and closed the skipway. The lessees in most of the cases made good 'stakes' from the leases. The company had poor steel conditions; not only insufficient steel, but the heat treatment was very poor. The lessees had one of the best men on steel to be found. There are hundreds of cases of this kind in the country, where the cause of loss is due to neglect of the fourth factor alone.

Before considering the remedy for this state of affairs, the question of the loss of steel in the mine should be considered. This decides the quality of steel in some cases. Managers will often state that they use cheap instead of high-grade steel because the financial loss due to the losing of steel underground is greater than the saving made by the use of high-grade steel. In one mine in California, 600 new drills were sent underground and within six months only 150 were left. By searching the mine thoroughly, about the same number were found hidden or thrown in obscure places. So in six months half of this new steel was lost.

A Good Way to Distribute Steel

To secure the highest efficiency in drilling, each machine man should have, on arriving at his working place, a complete set of drills, properly sharpened and heat treated. This could be accomplished in many mines by having the mine carpenter build a rack for each working place, or else iron racks could be made in quantities. Each should have two compartments with different locks. The rack should be kept as close to the working face as practicable. When the machine man comes on shift in the morning, he finds his complete set of drills near his work. On finishing his round, he replaces all the drills, dull ones 'bit' upward. The night men also find a complete set of sharp drills in their compartments of the racks. During the night shift the

'nippers' would take out all the dull steel from the day shift's compartments and return sharp drills later on. The 'day nippers' would handle the night shift's drills. The steel for stoping machines should be near the manways into the stopes. Keys to the racks should be turned in at the end of each shift, and the shift bosses should see that each machine man, on coming on shift, is given a key to his rack. 'Nippers' should have master keys to the compartments holding steel of the *opposite* shift, while shift bosses should have the master keys to the compartments holding steel for *their* shift.

By the use of this system the best quality of steel could be purchased, as the loss from missing steel would be cut down to the minimum.

Heat Treatment of Drill Steel

The heat treatment of drill steel has a more important bearing on drilling efficiency than any other one factor. The effects on drill steel due to improper heat treatment may be classed under the following heads: (1) dulling of the cutting edge of the bit; (2) breaking of the bit, due to 'checking'; (3) loss of gage.

The first entails loss of power due to the crushing of the rock, instead of its being chipped. This means less footage or else necessity for more drills. Breaking of the bit due to imperfect cooling, causing the drill to 'check,' may mean the loss of a hole, decreasing the effective footage drilled. The last effect, however, is the one that causes the greatest losses in efficiency. Drills that lose their gage rapidly may cause loss of holes, due to the fact that the next longer drill will not follow. In attempting to make a bit follow one that has lost its gage, much time and energy is wasted. The psychical effect on the miner is of great importance also. Often the machine will have to take the punishment, a sledge being used to loosen the bit and sometimes the blows fall on the piston rod or other vulnerable parts of the machine.

The loss of gage is due to the corners of the bits being too hard or soft. In the first place, the corners chip off and in the latter they rapidly wear, especially if drilling in abrasive rock. The heat treatment, in most mines today, depends on the eye of the blacksmith or helper. As it is impractical to draw temper on large drill steel, the heat treatment is generally conducted as follows: After sharpening, the steel is allowed to cool below the 'cherry red' temperature and then is given a 'short' heat. This means that only the extreme end of the drill, for a fraction of an inch, is heated to 'cherry red.' It is then 'quenched' thoroughly. The cutting edge is therefore of hard, untempered steel (fine grained, porcelainic texture), cushioned by a large mass of soft steel behind it. If the 'heat' at quenching is too short, the hardened portion will also be too short, and in drilling hard rock, will be driven back into the cushion, deforming the shape of the drill. If the heat is too 'long,' the cushioning effect is not sufficient and the corners chip off. Should the length of the heat be correct, the drill will stand up satisfactorily against the hardest rock, provided high-grade steel is used. As the color of the heated bit varies under different conditions of sunlight or artificial light, it is difficult to find a man who is able to heat and quench at the proper point.

The following method might be used in eliminating the human equation: The steel to be treated could be placed in a bath, heated by gas, gasoline, distillate, or electricity. This method of refining and tempering is used in automobile and tool steel manufacturing. A bath of $BaCl_2$ and KCl mixed in proportion of two to one would give a mixture that melts at 670°C. As the proper heat for refining steel is about 720°C., this bath would be all right. The control of the heat must at present be by hand, as there is no automatic device on the market that will stand up under working conditions. A pyrometer, with a galvanometer, would be necessary, so that each bath could be maintained at a certain temperature. A stirring device also would be needed to keep the bath at a uniform temperature. The steel could be placed on an iron rack, suspended at each corner by an iron rod. Horizontal side and end rods, sliding on the vertical corner rods, would hold the steel vertically in place and also allow each piece to be placed in and taken out readily. The rack could be raised or lowered into the molten bath to any desired depth. By holding the temperature at 720°C. for ordinary drill steel, and then quenching thoroughly, the cutting edge would be refined and uniformly hardened. The drills would not be really tempered, as in case of 'drawing temper' in hand steel, for no 'temper' is drawn after the quenching at 'cherry red' heat.

If more attention were paid to the questions of sufficient steel at the working face and proper heat treatment of the steel, higher efficiency and lower costs would result. Several of the largest mines are going into the question of heat treatment, but the great majority of the mines are leaving this important factor to the blacksmith.

State aid to the mining industry in New Zealand includes subsidies to prospecting associations, loans for development of promising mines, grants for construction of roads and tracks on goldfields, free use of diamond and Keystone drills for prospecting coal and alluvial gold, supply of water for hydraulicking at certain rates from government water systems, subsidized schools of mines at six centres, gold-miners' relief fund, work of the geological survey, and considerable help to prospect the deep levels of the old Thames goldfield in the North Island.

Plumbago stocks in Ceylon are small, and the war has affected prices considerably. Dealers who are forced to sell accept $65, and those who can afford to hold their stock want $114 per ton.

Tin and tin-ore exports from the Federated Malay States in 1913 amounted to 50,131 tons of metal valued at £9,758,422, compared with 48,421 tons worth £9,814,437 in 1912.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Stabilization of the Copper Market

The Editor:

Sir—Mr. Burton was, apparently, not thoroughly familiar with the safeguards which have existed in the international copper markets prior to the war. An active metal exchange trading in copper existed in London and in Hamburg and large commitments were made on both of these exchanges. Both exchanges were closed at the outbreak of the war. There is some talk and a probability that the London Metal Exchange will open next week. The Hamburg Metal Exchange has been liquidated by order of the German government and will remain closed during the war. Even if there were an exchange in New York with free trading in copper, this exchange would have had to be closed at the outbreak of war—just as the stock exchange, the coffee exchange, and the cotton exchange had to be closed. I do not believe that the method suggested by Mr. Burton would be a protection in a case of such extraordinary emergency as has been experienced during the past few months.

The only possibility of protecting the copper industry of this country against demoralization would have been co-operation on the part of the producers. Such co-operation, however, was not feasible on account of the stringent laws which have been enacted in this country against any combination in restraint of trade. It is perfectly clear that with the termination of war, copper will be much more valuable than it is now, and this was recognized from the very beginning by the individual producers; and it was also recognized that it would be much better in the interest of everybody concerned if the price of copper could be maintained on a fairly reasonable level, but in spite of all this, we have witnessed an extreme demoralization of the market; the closing down of a large percentage of the producing capacity of this country; great distress among the laboring classes and dissatisfaction among the stockholders of the various mining companies which had to forego the usual dividend payments.

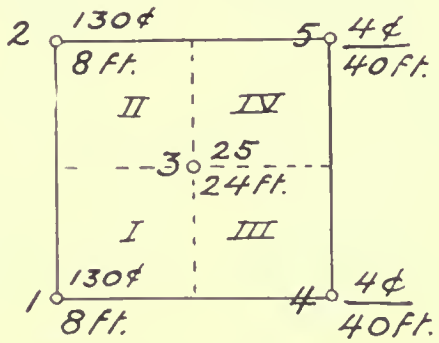
New York, November 6.

Valuing Placer Ground

The Editor:

Sir—The weight which should be given to the result of a prospect hole is obviously proportional to the volume represented by the hole, multiplied by the value per unit volume. In the particular case under discussion a correct method of procedure is illustrated by Mr. Herrick.

Mr. Hohl would have arrived at the same result had he given the interior, side, and corner holes their proper respective weights. That would have required his dividing the area into equal triangles instead of into triangles and squares, and would have given him a ratio of 4:2:1 instead of 4:3:2 as used.



Mr. Jennings has assumed that the average value of each of his eight subdivisions is represented by the arithmetical mean of the two holes on opposite corners. His results approximate those of Mr. Herrick in this instance, and consequently the error in the method is not sufficiently emphasized. It will be more apparent if the method be applied to the following hypothetical case where the average value for the block 1, 2, 5, 4 is 25c., and the result of Jennings' method is 35.5c.

Hole 1—130 × (8 × 0.25 = 2) = 260
2—130 × (8 × 0.25 = 2) = 260
3— 25 × 24 = 600
4— 4 × (40 × 0.25 = 10) = 40
5— 4 × (40 × 0.25 = 10) = 40

48) 1200

Average value 25c.

Jennings' Method

Area I. $\frac{130+25}{2} \times \frac{24+8}{2} = 77.5 \times 16 = 1240$

II. $\frac{130+25}{2} \times \frac{24+8}{2} = 77.5 \times 16 = 1240$

III. $\frac{25+4}{2} \times \frac{40+24}{2} = 14.5 \times 32 = 464$

IV. $\frac{25+4}{2} \times \frac{40+24}{2} = 14.5 \times 32 = 464$

96) 3408

35.5c.

Where the drill holes are placed at equal intervals over the area prospected, it will ordinarily be sufficiently

aeeurate to add all of the produets of 'depth by value' and divide by the sum of the depths. It is not probable that there would be a sufficient number of holes at the extreme edges and corners of the area to warrant special consideration.

DONALD STEEL.

Palo Alto, California, October 16.

Design of the Plymouth Mill*

The Editor:

Sir—Mr. Caetani is to be congratulated on his courage in designing the Plymouth mill as he did, and still further eongratulated upon giving such an exeellent deseription of it to the profession. Undoubtedly the next mill he builds will have no stamps, they being replaced by either rolls or ball-mills. Still, however, it is wise not to make changes too radieal to begin with.

His deductions in regard to the effeet of fine crushing inereasing the amount of colloids does not agree with our experienee at Miami. We are inclined to believe that the colloid in an ore is a fixed amount and that no grinding produees of itself colloid material. Apparently the colloid is in the fine cracks and seams in the roek, and is simply liberated by crushing, and not produeed by it.

J. PARKE CHANNING.

New York, November 12.

The Editor:

Sir—Referring to Mr. Caetani's article appearing in your issue of October 31, I note that Mr. Caetani has experienced some trouble with his elevators. If a few suggestions are not amiss, permit me to offer them. It may relieve him of some of the trials and tribulations pertaining thereto. It is agreed that all elevator work is a bugbear to mill-men.

In the first place the head pulley eomes loose on the shaft. The shaft he describes seems to be of sufficient size for those elevators. Now why not shrink the pulley on the shaft by having the pulley bored and the shaft turned down so as to make a 25 or 30-ton fit, and have two keys fitted in and set-serewed? Then I think the head pulley will entirely wear out.

Belt slipping and sliding off the head pulley is due to the fact that the head pulley shaft is not level and in line with the boot pulley, or the belt is too loose and needs to be shortened. The head pulley need not be lagged, not even to put an extra erown to it. Personally, I think a lagged pulley is a detriment, because if it be lagged with another belt and this heeomes soaking wet and slimy, then you do not have the same friction that you would have on a bare pulley. This is one cause of elevator belts slipping. If everything is all right and the belt starts to slip, shorten it as soon as convenient. It will save the belt eonsiderably.

By all means have a good grade of elevator belting. It will save in operating time and also in labor. An inferior belt will eontinually stretch, and if it does not stretch uniformly, some of the plies of rubber or canvas will be cracked and broken, or one side may stretch more than the other, thereby causing the belt to run crooked.

About onee a week or so, it would be well to shut the elevators down for an examination of buckets and splices, also for loose bolts around head-pulley shaft and boot-pulley shaft-bearings. The boot-pulley bearings described are good as far as they go, but if at the open end they were made so that a couple of rings of flax packing could be inserted, tightened, and drawn in place by means of a gland, it would help to keep out some of the sand, minimize the oil consumption, and prolong the life of the shaft.

In all elevators I think it best to have the feed enter the 'pit' or 'boot' on that side of the belt which is going up. There is then but one duty to be performed—that of elevating only. If the feed enters the pit on the opposite side, the buckets are compelled first to scrape all the feed from under the pulley and then elevate it, incidentally increasing the amount of power eonsumed.

I cannot agree with Mr. Caetani regarding the use of rubber washers between the belt and bucket. It is true that it reduces the wear between the bueket and belt due to attrition of fine sand, but on the other hand the bucket is not as firmly fastened to the belt when washers are used as when it is put on without them or even with a pad in between. When there are washers used, there is more of a hinge effect when the buckets go over the head pulley than there is when they are not used, hinging on the row of bolt holes. Consequently the fibre of the belt is injured to a greater extent and the belt is considerably weakened. Fasten the buekets on a belt both ways and see if the one does not offer less resistanee than the other. The best praetice, I find, is to use a pad made of an old belt, one that has been disearded is best; make it as wide as the bueket is deep and as long as the elevator belt is wide. The wear by attrition will be just as much on the pad as on the belt itself, which is not so very mueh. Any further thoughts or suggestions by others, in this connection, will be interesting.

J. H. LEWIS.

McGill, Nevada, November 16.

[Anyone who has run a mill remembers troubles with elevator belts and buekets, and such practical suggestions as Mr. Lewis makes will be widely welcome.—EDITOR.]

*'Design of the Plymouth Mill,' by Gelasio Caetani, *Mining and Scientific Press*, October 31, 1914.

ANTIMONY is used in the following alloys: Britannia metal, Sb, 10%; and Sn, 90%. Pewter, Sb, 7.1%; Bi, 1.8%; and Sn, 89.3%. Hard babbitt, Sn, 100 lb.; Sb, 10 lb.; and Cu, 10 lb. Softer babbitt, Pb, 80 lb.; Sb, 15 lb.; and Sn, 5 lb. Linotype metal, Pb, 83 lb.; Sb, 12 lb.; and Sn, 5 lb. Electrotype metal, Pb, 100 lb.; Sb, 10 lb.; and Sn, 5 pounds.

GOLD OUTPUT of the Ouro Preto mine, Brazil, in September was $41,200 from 6050 tons of ore.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

CYANOGEN occurs in coal gas as free cyanogen, CN_2, and hydrocyanic acid, HCN, both of which are gases. It is formed by the combination of a small percentage of nitrogen contained in the coal, with the necessary amount of carbon. The amount occurring in the gas is dependent on the temperature of distillation. A temperature of about 1735°F. is about the most favorable, according to C. C. Tutwiler in the October *Journal* of the Franklin Institute. The yield of HCN will then be 2 to 3 oz. per 1000 cu. ft. of gas. The Knubbauch system is the basis of the Feld, Stavorinus, Bueb, and British cyanide processes of manufacture.

BOULDERS weighing up to 50 tons each are lifted by the 15-cu. yd. Bucyrus dipper dredges *Gamboa* and *Paraiso* at the Culebra Cut, Panama, and the method of handling these large rocks is interesting. Instead of drilling and shooting them, as is the usual custom on contracting jobs, the Panama engineers 'mud-cap' them on the dipper. In the former instance 1 to 1½ hours is consumed, in the latter a space of about 3 minutes. As a general rule, long boulders, with dimensions of about 12 ft. long by 15 to 20 ft. in circumference, are thrown back in the water and an attempt made to catch them endwise in the dipper, so that they may pass through when the dipper is tripped. This also offers a chance that the rock may be broken in two by the dipper. If this method fails, the boulder is laid across the dipper and mud-capped. As a rule, a charge of from 2 to 4 lb. of dynamite is used, and as high as 6 lb. as a maximum. Round and egg-shaped boulders which are too big to pass through the dipper are mud-capped. As a general rule, where mud-capping is necessary, the boulder is lowered a few feet below the surface of the water so as to prevent the flying of rock. The dipper door is kept open when this operation is going on.

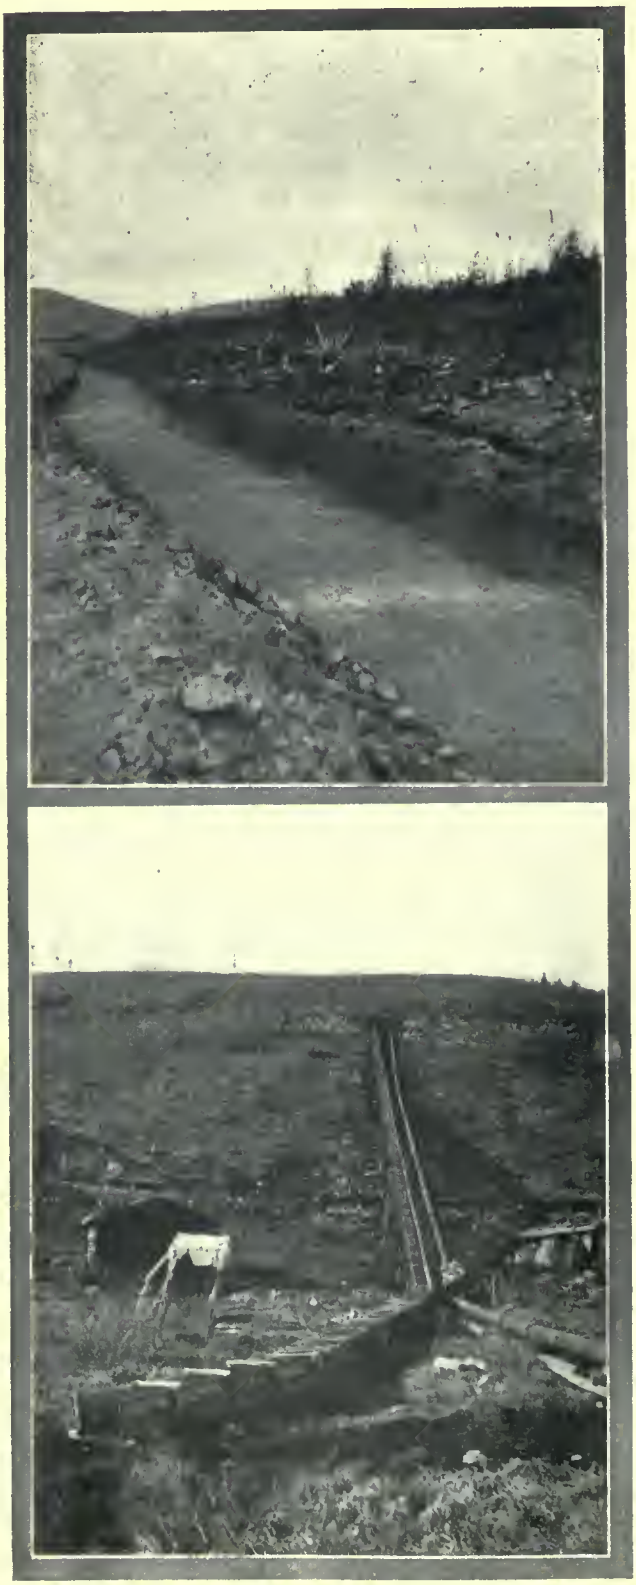
MINE INSPECTION in Western Australia, as in other states and New Zealand, is strict, and in the western state, including the state mining engineer, there are 13 inspectors for the various goldfields and mineral areas. These fields cover an area of 329,828 square miles, scattered through which are 1464 leases or properties with an area of 21,382 acres. There are nearly 15,000 men employed at these mines. The inspectors have a wide scope of power in maintaining the government mining regulations, and during 1913 there were 103 charges brought against various persons for breaches of the act. Fines were imposed in 97 cases, against men from general managers down to prospectors. Inspectors are appointed on their merits as mining men, for life, being chosen by suggestions of the Chamber of Mines at Kalgoorlie, the mining engineer, A. Montgomery, and others. No elections or politics enter into placing these responsible men in their positions. In addition to the mining inspectors, there are a superintendent and an inspector of the 37 government-owned custom mills and treatment plants, in charge of 17 managers; and eight inspectors of machinery, including the chief inspector, who made 3988 inspections in 1913, covering 2980 useful boilers and 3422 different classes of machinery, the total value of all mining machinery being approximately $18,300,000. The last named inspectors are strict and secured convictions in several cases for non-compliance with the regulations. There is also an inspector of explosives, who is the government analyst and chief chemist. All inspectors' reports are published in the annual report of the State Department of Mines.

ANTIMONY is used in comparatively small quantities in a great variety of ways, in the form of its numerous compounds. The impure trioxide is used to some extent in making glass, especially for that variety known as 'strass,' from which imitation jewels are made. It is also used as a substitute for tin oxide in the making of enamels, and the Enamel Company of America, with a plant at Elyria, Ohio, is using a quantity of antimony for this purpose. Enamels containing antimony are prohibited by law in Europe, and there is a possibility, of course, that similar legislation may sometime be passed in the United States. The oxide is also used in the making of lithopone, and to a small extent as a pigment in paints. It cannot be regarded as in any sense a substitute for lead or zinc pigment, but is merely used for mixing with them, as it is now generally recognized that mixtures of various pigments are more satisfactory for many uses than any single one. Tartar emetic is used in medicine. There is a tendency now to replace that by the use of the double fluoride of antimony and ammonium, and also by the double salt of ammonium sulphate and antimony fluoride. The pentoxide of antimony is also used in the manufacture of aniline red and aniline yellow. The trisulphide of antimony occurs in several isomorphic forms. The red form is known as antimony cinnabar, which is used as a pigment in oil painting. Antimony yellow has some uses. The sulphide of antimony is used to a certain extent in the making of matches, glass, and also for lithopone, where it is treated with barium carbonate. The double fluorides of antimony are used to a certain extent as mordants. The total amount of antimony thus consumed is not great.

MINING IN THE FAR NORTH

The Klondike, the Treadgold Placers, and Outlying Districts

By EMIL EDWARD HURJA



DITCH BETWEEN CARIBOU AND NEVADA CREEKS; PIPE-LINE AND WASH FLUME FROM DITCH ON GRANVILLE CREEK.

Over $180,000,000 in gold is credited to the Klondike as the production since gold mining first started in the Yukon. The greatest single year's production was $22,275,000 in 1900. The 1913 production was $5,500,000, and indications are that the 1914 production will be about the same. Gold mining in the Klondike has settled down to a steady annual grind, without the uncertainties of the earlier days. Mining is a business there now, not a gamble.

Early History

In 1894, Robert Henderson and two other miners prospected the gravels at the mouth of Pelly river, where they rocked out $54 in fine gold. They came down to the mouth of Indian river, which Henderson ascended alone and prospected on Quartz and Gold Bottom creeks. In the spring of 1895 Henderson and a party of five men returned to Gold Bottom to conduct a further search for gold. Encouraging prospects had been found the summer before by Henderson. Henderson told George W. Carmack of the discovery that summer and invited him to stake on Gold Bottom creek. This Carmack did, but as he was returning from there, he did some prospecting on Bonanza creek and found rich prospects. The claims were recorded and a stampede of miners from the Fortymile district started. Soon Bonanza creek was staked from end to end. When news of the rich discoveries penetrated to the outer world, thousands of people immediately started for the Klondike. Perhaps the Klondike stampede was the greatest in history of gold mining camps in the world. At any rate, the route to the fabled diggings led over a rugged mountain chain, down lakes and rivers over five hundred miles to Dawson, the camp which grew about Klondike's sands, and this route was black with people. The outlying creeks were staked soon and millions started to pour out in gold. Bonanza and its tributaries was probably the richest creek in the Klondike. Creek Claim No. 16 on Eldorado, a Bonanza tributary, produced $1,500,000, while the claim next to it produced $1,300,000.

Primitive placer mining was with the pan; then came the rocker. The ground was thawed with a succession of wood fires, found to be the cheapest and most effective means of taking the frost from the gravels. The hand windlass, used in hoisting the dirt from the bottom of the hole to the surface, soon was replaced by a steam hoist. Steam, led through pipes from the boiler, replaced the wood-fire method of thawing. The dump was first made near the shaft, but the carrier was evolved, and it became possible to dump the gravel farther away. Sluice-boxes and running water did away with the rocking.

Then came the open-cut method, where the overburden of waste was removed and the gold-bearing gravels were thawed by the sun, to be scraped into the sluice-boxes in wholesale fashion. Dredge machinery then was brought into the Klondike. At first the dredges were operated by steam, now all are driven by electricity. Ground is thawed ahead of the dredges by steam points driven down from the surface. Now even the thawing process is being eliminated. The ground is scraped off, the 'muck' and waste gravel removed, and the sun does the rest.

The big companies operating in the Klondike are the Yukon Gold Co., owned by the Guggenheims, the Canadian-Klondike, and the North West Corporation, Ltd., controlling the Granville Mining Co., Ltd. and the Treadgold holdings. Two

of these have been described. There are some individual plants yet, but they are confined to the outlying districts. There is some quartz mining, but that development has been slow.

Treadgold Placers

In preparation for the arrival of a Lubecker link-bucket excavator, part of the ground comprising the holdings of A. N. C. Treadgold and associates is being cleared. The work is in progress on three streams, Dominion, Granville, and Quartz creeks, and because of the large-scale method of clearing the frozen 'muck' and overburden from the claims, comparatively low costs have been attained.

Under the supervision of Gus Bredenberg, manager, three stretches about a mile long and from 125 to 300 ft. in width have been prepared. The scrub timber first is removed, then the 'muck' and some waste gravel. It has been demonstrated that the covering of 'muck' keeps the frost in the ground and prevents natural thawing. It is the plan of the Treadgold engineers to open sufficient ground ahead of the excavators to give it ample time to thaw without the use of steam. Measurements are being taken to show the rate of thaw in the gravel, and what little work of this nature has been done is promising.

Water for the ground-sluicing operations is being obtained through a system of ditches 21 miles long. The capacity of the ditch is 600 in. per minute. From an intake at Burnham creek, the ditch runs up the left limit of Dominion valley a distance of eight miles to Jensen, where a dam has been built. The ditch crosses Dominion there and follows the right limit of Dominion valley, crossing Gold Run creek, to 245 Below discovery, Dominion creek, where the pipe-line starts. Another ditch eight miles long has an intake below the mouth of Caribou creek, a tributary to Dominion on the right limit. The ditch follows the left limit of Dominion creek, catching all the water from the smaller side streams. At the lower end of the ditch, there is a head of 207 ft. Water for hydraulicking is used through two 3-in. nozzles. After being used, the water flows into Dominion creek, to be caught at Jensen and used again in the lower ditch.

The object of the hydraulicking is to expose the gravel or solid bottom below the ice belt of the 'muck.' Considerable ice in layers and sheets has been found in the 'muck,' giving trouble in the ground-sluicing. The 'muck' has a thickness, determined from the work accomplished this year, of from 12 to 17 ft. Sluiced from the claims, it has a tendency to lodge in the old stream bed, but no difficulty has been experienced as yet from this source. The first heavy rain usually is effectual in cleaning out the channel. Where the original channel of the creek is tortuous, in some instances it has been straightened, thus giving the stream a better grade to carry off the refuse 'muck.'

SEAMS OF ICE AFTER THE THAWED 'MUCK' HAS BEEN HYDRAULICKED OFF.

To July 1, on Dominion creek, a total of 774,294 yd. had been cleaned; on Granville creek, 790,173 yd.; and on Quartz creek, a total of 1,027,070 cu. yd. The monthly rate of disposal of 'muck' has been, on Granville, 191,666 cu. yd.; on Quartz, 143,362 yd. This has been accomplished with an average daily capacity of about 500 in. of water. Once removed, the 'muck' is never handled again in the mining operations. The daily thawing rate of the frozen 'muck' has varied from two to three inches. The nozzles are moved from three to five times a day, in order to take as wide advantage of the thawing as possible.

Actual work on the ground-sluicing started in May 1913, although no determined attempt was made until the present summer. The three creeks have been opened for a length of one mile, and the work is being directed toward widening the strips of cleared ground. Thirty men have been employed on each of the three creeks. The monthly payroll has been between $5000 and $5500. The power-line is partly constructed from the north fork of the Klondike. Work on it will be completed this year, it is expected.

Mr. Bredenberg estimates the cost of removing the 'muck' to be about three cents per yard, although monthly balances early during the progress of the work have shown costs as high as 7.7c. The 1914 costs on Granville creek have been 1.6c. per yard; on Quartz, 5c. per yard; and on Dominion, 6c. per yard. These costs will decrease still more, it is the claim of Mr. Bredenberg, as the overhead cost becomes less.

The Lubecker excavator which Mr. Treadgold plans to use on the properties, runs on two sets of rails, laid along the ground a distance of a mile. Eight-foot buckets travel at the rate of eight feet per minute, scraping off from two to four inches of gravel each trip, according to the rate of thawing. It takes the bucket line 12 hours to

MONITOR AT WORK ON 35 BELOW DISCOVERY, LEFT LIMIT, DOMINION CREEK.

GRANVILLE GROUND CLEANED FOR THAWING, WITH OLD TAILING PUMPS IN THE BACKGROUND.

GRAVEL IN FOREGROUND READY FOR THAWING; 'MUCK' IN BACKGROUND.

travel the mile stretch of ground. It is said that Lubecker excavators are in successful use in the Amur district (of Siberia) for the Upper Amur company. Mr. Treadgold has options, running mainly for one year, on considerable other ground in the district.

Outlying Districts

On the Sixtymile, above Dawson, mining is in progress on Tenmile creek, a tributary. Some rich ground is reported to have been found there during the past year. The bulk of Sixtymile river is optioned to the Yukon Gold Co., at $3000 per claim. Keystone drills have been used in prospecting, and it is likely that more will be done during the coming winter.

Stewart river, south of Dawson, is the scene of considerable mining activity. In the upper Stewart, on Minto lake, Kastner & Scougle have spent $40,000 to prepare for their hydraulic operations. Seven miles of ditch has been built, which will give unlimited water for their work. They have a fall of 225 ft. in one mile. On Highet creek, Elmer Middlecroft, of Seattle, is hydraulicking. Three thousand dollars was cleaned up late in the summer after a 10-day run with seven men at work. On Haggert creek, several placer outfits are at work. Abbott & Portlock employ 14 men. They have a ditch and a 1500-ft. pipe-line. One small company is prospecting hydraulic ground on Secret creek, a tributary to Haggert. On Scroggie creek, there are 20 outfits at work. More will work this winter. A government road has been built to the upper Stewart district.

On Dublin gulch, a tributary of Haggert, Catto & Stewart have a group of eight quartz claims. Five hundred feet of adit has been driven. The vein is eight inches wide. The ore is said to be free-milling. Robert Fisher, on Olive creek, has had ore that assayed well. Frank Carscallen is prospecting.

The most recent excitement in the district was the silver-lead find of Harry McWhorter on Galena creek, a tributary of McQuesten river. The new government road to that area follows the Mayo road to Minto bridge. From there, the new Haggert Creek road is followed for six miles. The government has just completed the new stretch of road from that point to Galena creek, a 12-mile stretch. On the Galena claim, the discovery claim staked by McWhorter, the vein has been cross-cut on both sides of a narrow cañon which cuts the lead. The bottom of the cañon shows a depth of 55 ft. on the vein. An adit has been driven along it 65 ft., and 60 tons of ore mined and shipped. This summer a shaft was started on the upper outcrop to intersect the adit. The shaft is 95 ft. deep, 40 ft. below the adit level. The vein varies from 2 ft. to 2 ft. 8 inches in width. With depth, ruby silver is more abundant. Specks of native silver have been found in the ore.

Eighty claims have been staked in the district. Seventy-five men are at work there. Active development is under way on only four other claims. The mineralized belt of which the McWhorter lead is a part has been traced across country for three miles, according to F. H. Kitto, former director of surveys of Yukon Territory, who recently came out of the district. McWhorter is asking for tenders on freighting out a shipment of 1000 tons of ore. He is building winter quarters at the claim and intends to carry on development all the year round. McWhorter first found galena float in the district 12 years ago, but he did not think it warranted further effort until a year ago, when he decided to go in and prospect.

The MacKinnon Brothers own a group of 20 claims 30 miles from Dawson on MacKinnon creek, a tributary of Indian river. A deposit of limestone conglomerate has been found on the claims and is being developed slowly. On the Britannia claim, a 20-ft. adit and a 60-ft. shaft comprise the development work. The conglomerate pans well.

Other quartz properties in the vicinity of the Klondike are the Lone Star, at the head of Victoria gulch, where a six-stamp mill is operating under the management of E. H. Searle, and the Bear Creek Mining Co., operating a small mill on Bear creek. Murray Eads is manager of the latter concern.

The Gold Commissioner at Dawson reported that in August, Dan Cadzow, the trader at Rampart House, on the upper Porcupine, came down for supplies and while there asked that Sergeant Dempster, of the R. N. W. M. P., be appointed an agent to the mining recorder and be supplied with the necessary blanks for recording mining claims staked in the upper Porcupine district. Cadzow said that prospects had been found, but nothing that would justify even the slightest kind of a rush.

The Fortymile district, though lying on the American side of the boundary, has been tributary to Dawson ever since that place was founded. There is considerable mining work in progress in the Fortymile, although most of it is on a small scale. William Obermuller and Paul Denhart have uncovered encouraging prospects on the middle fork, but because of trouble from water, have been forced to postpone prospecting it until this winter. On Gold creek, a tributary to Slate creek, which empties into the north fork of the Fortymile, two outfits were working this summer. Three outfits, owned by John McLain, E. M. Webster, and Ostergaard & Kirkpatrick, were at work on Hutchinson creek.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BUTTE, MONTANA

General Situation of the District.—Labor Discussion.—Electrical Workers Hold Up Important Construction.—Pittsburgh and Gillmore Railroad.

Butte is holding up under the general business depression, caused by war and the price of copper, much better than had been expected. No business failures of importance have occurred as yet, and with characteristic optimism the community is hoping for better things, and making the best of the situation.

The only additional mine to close down recently was the Butte & Superior. This was unfortunate because of the number of men affected at both mine and mill, but was not due to the price of spelter. The cause of the shut-down was an accident to the working shaft, which has been in bad shape for some time. As the shaft in question is the only one available for hoisting ore, and is depended on for hoisting over 30,000 tons of ore per month, it was considered necessary to close the mine and mill entirely until the shaft could be put in first-class condition. This work is now under way and should be completed by the first of the year, when it is expected that the property will start at full blast again. Nearly 1000 men were thrown out of employment by the closing of this property. The last quarterly report of the Company is given on page 861 of this issue.

Some of the large companies are trying to keep their technical staffs intact in spite of shut-downs. They are accomplishing this by offering the men reduced pay during the dull times. Some of the heads of departments have voluntarily reduced their salaries, as much as one-half in some instances.

No disorder and no increase in crime seem to have resulted from the enforced idleness of so many men. In fact, the number of idle men in Butte does not seem to have greatly increased. Apparently many of the men thrown out of employment have considered it useless to wait about for a return of conditions to normal, and have left the city in search of employment elsewhere.

This centre has apparently weathered a most important labor crisis with little damage. In fact, no one would have predicted such a peaceable outcome for such a great change. It is possible that our perspective is sufficiently good now to review in substance the events leading up to the present situation:

Last spring considerable dissatisfaction began to be openly expressed by the miners over the management of Butte Miners

GENERAL VIEW OF BUTTE & SUPERIOR PROPERTY.

1. Carpenter and Timber Framing Shops. 2. Machine Shop. 3. Head-Frame. 4. Miners' Change-House. 5. Secondary Crushing Plant. 6. Mill Building. 7. Assay Office. 8. North Butte Extension Property.

Union No. 1 of the Western Federation. Complaints were made against excessive taxation, mismanagement of funds, suppression of free speech at meetings, unfair judging at elections, and tyrannical action of union officers. These allegations finally resulted in open dissatisfaction against the union, personal threats and attacks on the officers, and the final, violent destruction of the records, property, and building of the union. The next move was the organization of a rival union, and for a time the two organizations strove peaceably for the support of the miners. Finally the new organization began to use violent means for the suppression of the older one, and began to deport its supporters. Up to this time the operators had succeeded in keeping out of the controversy, but one night late in August the employment office of the Anaconda Copper Mining Co. was dynamited by persons who apparently wanted to show their disapproval of this method of employing men. This was the 'straw that broke the long suffering back of the Company's camel'; the militia was called in to keep order, and the mine operators announced that they had enough of such tactics, and would refuse to recognize any union at the present time. In other words, open shop was declared for the Butte mines, and men can now work in Butte as miners without showing allegiance to the Western Federation of Miners, or any other union. The militia had little work to perform, as the miners remained peaceable, so that it has been dismissed recently, and the community is again controlled by the civil authorities. About the only change compared to conditions before the trouble is that street oratory is tabooed by the sheriff, and I. W. W. agitators are unceremoniously advised to keep moving. In view of the uncertain financial outlook for the community at best, the citizens do not intend to be imposed upon by soapbox orators, and their disturbances may be expected to be summarily dealt with. The mining companies are taking no chances on future events, however, and have enclosed their properties with high board fences, and other means of protection. Searchlights are in use at night so placed as to illuminate any part of the properties.

The work of electrifying a Montana division of the Chicago, Milwaukee & St. Paul railway is to be resumed forthwith. The Electrical Workers' Union caused the cessation of this work some months ago by demanding that the laborers who erected the poles, on which the electric wires were to be strung, should be classified as electricians and receive electricians' pay. This action, however, 'killed the goose that laid the golden egg,' for the Milwaukee officials refused to yield to such absurd dictation, and stopped all work on the electrification. Fortunately for all concerned, the union has been given an opportunity to back down gracefully. The Montana Power Co. has taken a contract from the railroad company to install the apparatus, and the union has condescended to let the power company employ whom it pleases to dig post holes and set up posts. The power company is naturally very much interested in having the electrification of the line pushed to completion, as it has a large and important contract with the concern for furnishing power, and is building large hydroelectric plants at Great Falls and Thompson Falls to supply the power. It would hardly appear as if our 'great and glorious democracy' is working to best advantage, when a handful of greedy mechanics can hold up for months an enterprize involving the expenditure of millions of dollars to the advantage of the community.

The puzzle has at last been solved, and the Northern Pacific Railroad Co. openly avows ownership of the Pittsburgh & Gilmore line. Several years ago this branch was built into the Salmon River country of Idaho, and joined the Oregon Short Line at Armstead, Montana. The traffic rates were high and the service poor, although everyone had to confess that the railroad was a great improvement over the old stage days. Some mines profited by the railroad and other prospects were developed because of it, but complaint was general that the service was inadequate and the rates exorbitant. Speculation was rife as to who owned the road, all the western railways being mentioned at one time or another, but it is very probable that none of them were guilty. The road was apparently built as a speculation by some Pennsylvania capital that was interested in mines tributary to the railroad. The burden of operating the road was apparently a heavy and profitless one, so that everyone is probably benefited by the passing of ownership to the Northern Pacific interests. It is not improbable that this concern may in time extend the road on down the Salmon river to Lewiston, Idaho, and thereby open a mineral country which has long needed transportation facilities.

DEADWOOD, SOUTH DAKOTA

HOMESTAKE COMPANY'S CONSTRUCTION WORK.—MONUMENT TO THE LATE SUPERINTENDENT.—MINE INSPECTOR'S REPORT.—GOLDEN REWARD, HEIDELBERG, ECHO, AND OTHER COMPANIES' WORK.

New construction work at the Homestake is proceeding rapidly. At the B. & M. shaft the brickwork for the walls of the engine-house has been completed, and the steel roof girders erected; and in a short time the roof will be covered. All of the machinery has been delivered. The great engine is ready for erection as soon as the building is complete, and work on the steel head-frame and shaft-house will soon be started. In the meantime the shaft is being used every day, the old hoisting engine, in its day the finest in the Black Hills, being employed in hoisting ore. The new engine will hoist in balance eight-ton skips of rock. Its capacity is rated at 3000 ft. At the electric generating station, work of erecting the building is well under way. All foundations and retaining walls are finished. Machinery is also on the ground for the equipment of this plant. At the boiler plant, where steam will be generated for the hoist and electric plant, foundation work is being completed. Here it has been necessary to sink 20 to 30 ft. to hardpan, on which to rest the concrete carrying the heaviest bearing portions of the superstructure and equipment. On these three structures, with their various equipments, at least $250,000 will be spent before completion. They will form important units in the Company's extensive surface plant.

In memory of the late superintendent, T. J. Grier, the Homestake Veterans' Association has decided to erect a monument or other suitable memorial, on grounds between Recreation Hall and Christ Church, at Lead. That all interested may have an opportunity to contribute to the construction fund, the maximum of donations to the fund has been placed at $1. So far, employees of the Company have raised a little over $1500. It has not yet been stated how much has been received from other sources, but it is known that this also amounts to a considerable sum. It is proposed to erect a monument of substantial proportions, with inscriptions commemorating the history of Lead's greatest citizen, who was the friend of all and loved by all.

The state mine inspector, O. Ellerman, in his report for the year ended October 31, states that the gold production of the Black Hills for that period was $7,325,510. This is a decrease of $171,589 compared with the previous year. A large proportion of the ores handled in the state are worth less than $4 per ton, although there are considerable shipments of smelting grades. The average value of the ores treated during the year is given at $3.68 per ton. Various mines produced as follows: Homestake, $6,046,000; Golden Reward, $369,182; Trojan, $357,229; Wasp No. 2, $229,390; Mogul, $141,298; Bismarck, $83,919; New Reliance, $69,532; Deadwood Standard, $7238; Placer mines, $1800; and miscellaneous, $19,920. Other minerals than gold were produced, chiefly in Pennington and Custer

counties, as follows: mica, $6150; gypsum, $59,000; tungsten ores, $400; lithia ores, $1150; lead, $811; and beryl, $538; a total of $68,049. The report shows 3040 employees in the mining industry in the Black Hills, of which 1344 are underground workers, the lowest wage scale for any of them being $3 per day of 8 hours. There were 4 fatal accidents and 10 non-fatal accidents during the year.

During the past summer the Golden Reward cyanide plant, at Deadwood, has been improved and enlarged by the addition of a tube-mill, a 24 by 16 ft. Trent replacing tank, 2 agitators, 1 Akin, and 1 Dorr classifier, and several secondary machines. The plant is now equipped to handle ore as received from the Astoria roaster. This material is slimed in the tube-mill, and although it is extremely hard, a satisfactory tonnage is being treated.

Now that a depth of 58 ft. has been reached in the shaft being sunk at the end of the adit at the Heidelberg, plans are maturing for the installation of a steam plant, work to date having been done with a windlass. It is proposed to raise to the surface a distance of about 100 ft., and there to erect machinery suitable for continuing work to quartzite, a distance variously estimated but probably less than 500 ft. It is interesting to note that the 'ore vertical' followed by the shaft has maintained its size and gold content for the entire distance sunk.

Machinery has been ordered by the Echo Gold Mining Co. to be erected at the shaft site, and sinking started. Equipment to be installed will include an electrically-driven hoist and compressor, air-hammer sinking-drills, drill sharpener, assay office, etc. The Company plans to sink several hundred feet. The property is stated to be on the northerly extension of the Homestake lodes, and is favorably regarded in local circles.

V. R. Hodges and associates, who, during the summer operated the Deadwood Standard property under lease, have suspended work for the winter. They had a satisfactory season, but shut down rather than go to the expense of making needed extensive repairs to the mill building.

Mills & McNish have in operation the only tin mill in the Black Hills, and probably the only one in the United States at the present time. The plant is equipped to pulverize the ores dry, with rolls; the pulp is later agitated with water and fed to Wilfley tables. No slime tables have been installed. The best grades of tin ore are being handled, and the plant is stated to be making money. It is situated four miles from Hill City, in Pennington county.

A small stamp-mill is being erected at the Liston property, near Keystone. The property shows a considerable tonnage of free-milling ore, a large portion of which can be mined in an open-cut.

The Hill City Mining & Development Co., operating near Hill City, is preparing to install a steam mining plant, consisting of hoist, compressor, pumps, etc. Development so far shows a good vein.

The Anaconda company, at Roubaix, is moving its hoisting plant to a situation 500 ft. north of the present 500-ft. shaft, and as soon as erected work of sinking several hundred feet will be started.

KALGOORLIE, WESTERN AUSTRALIA

Labor Unions Want More Wages in Certain Districts.—Great Boulder Company's Option on Mines in Victoria.—Chaffers Mill Started.—Mountain Queen Mine, and Refractory Ore in the Transvaal Property.—Horse-Shoe Development.

In spite of the disturbance of business caused by the war, and the increased cost of all mine stores by 25 to 30%, the miners' unions of Leonora and Menzies have cited a case to the Arbitration Court for an increase in wages. On the Chamber of Mines appealing to J. Scaddan, the labor premier of the state, to use his influence to get the unions to allow the matter to stand over till a more propitious occasion, the Chamber received the surprising reply that the request could not be complied with. In retaliation, the Chamber has cited a case to the Arbitration Court for a reduction of wages at Comet Vale and Ora Banda, where it is considered that the wages paid for some years have been excessive. With regard to the districts mentioned, the only capitalized mine in the Leonora district is the Sons of Gwalia, which has treated 2,317,300 tons of ore for a return of $20,513,250, and paid $4,986,810 in dividends. In the past two years the Company has been earning monthly profits of $25,000 to $30,000, of which half has been absorbed in thoroughly overhauling and adding to the treatment plant. This mine employs 300 men. As regards Menzies, only one English company is operating in the district, the Menzies Consols. During its 19 years existence the mine has produced $3,889,000 from 295,800 tons of ore, and, during this time, the shareholders have never received any return on their capital, and it looks as if they would never receive any. In addition to the proceeds of gold mined, an amount of $370,000 of cash, subscribed by British shareholders, has also gone in equipment and development. There are 90 men employed at the mine. At Comet Vale there are only three producing mines at work, all privately owned. Of these, only one, the Sand Queen, is a regular producer and dividend earner. Its record to date is $1,112,500 from 67,400 tons, and $352,500 has been paid in dividends. This mine employs 80 men. At Ora Banda the only company operating is the Associated Northern, which is working the Victorious leases. Owing to the grade of the available ore in the oxidized zone not being profitable, the mill was closed down in January, and since then $98,700 has been spent in development and equipment of a sulphide treatment plant, the engine for which has only just arrived. During the time the mill ran, 129,200 tons was treated for $698,800. When the mill was at work, 150 men were employed. Developments in the sulphide zone in this mine have, so far, proved unsatisfactory, and unless a great improvement takes place, there will be very little margin over working costs.

SANDSTONE, WESTERN AUSTRALIA. A TYPICAL MINING TOWN OF THAT STATE. PEPPER TREES IN CENTRE OF MAIN STREET. BUILDINGS PAINTED WHITE TO LESSEN HEAT IN SUMMER. ALTITUDE ABOUT 1500 FEET.

The combined labor unions are at present holding a prolonged conference at Kalgoorlie, and no less than 51 subjects are to be debated. Among others is the abolition of contract and bonus work; the abolition of night shift; the reduction of a week's work to 44 hours; that overtime be paid for at the rate of time and a quarter, and Sunday work at the rate of double time; and that shifts in rises consist of 4 hours only. The meeting has already carried resolutions referring the question of contract and bonus work to the state parliament.

and as Mr. Scaddan, the premier, has already stated in his election speeches that if his party is returned to power on October 21 he will re-introduce the Mines Regulation Act Amending Bill, which includes all the questions at stake, the object of the present conference does not appear at all obvious. If the bill is forced through in its entirety; many of the mines, which are merely making expenses, may be forced to close down, and a number of men will be out of work.

Richard Hamilton, manager of the Great Boulder, has just returned from a visit to the Moonlight-Magdala group of mines in Victoria, over which the Company holds an option. After unwatering the mine to 1200 ft., and sampling and diamond-drilling during six months, Mr. Hamilton has found the ore too poor to show a reasonable profit. Owing to the Victorian government offering to subsidize the prospecting work to the extent of dollar for dollar up to $50,000, or more if necessary, Mr. Hamilton has agreed to unwater the mine to 1400 ft. and further test it. The lode in the upper levels of the group was very rich, and $7,500,000 was paid in dividends, but the returns for 1912 totaled 14,350 tons for $65,970 or $4.59 per ton. The deepest shaft on the property is 2425 ft., but the lode was tested by a drill to 2700 ft. by the old owners with poor results. Mr. Hamilton promised, when taking the option, that if he was satisfied he would install a plant similar to that on the Great Boulder at Kalgoorlie and find employment for 600 men. As the Boulder's costs are $5 per ton, exclusive of depreciation, and London office expenses and directors' fees, the proposition seems hopeless.

The new treatment plant at the Chaffers mine at Kalgoorlie started operations on September 29, on a dump of 2000 tons raised during development work. This ore is estimated to be worth $9 per ton, and, after it is treated, ore from the mine will be stoped and treated. The ore reserves, at the time that the Company was reconstructed, amounted to 104,900 tons, worth $6.18 per ton, and on this grade it is estimated there will be a profit of 60c. per ton, or $3600 per month on an output of 6000 tons. Since the reconstruction, 1290 ft. of cross-cutting, 1155 ft. of driving, and 750 ft. of winzing has been done. The bulk of the ore developed assays from $6 to $7.20 per ton, but at No. 16 level No. 3 west branch lode assays $26.52 over a width of 6 ft. and a length of 181 ft. This lode is not developed at No. 15 and 17 levels. A month ago the Company came to the end of its cash resources, and the manager, Boyd Aarons, had to appeal to the men to continue working and await payment out of proceeds of first gold won. With few exceptions, the men agreed to this.

The Mountain Queen mine, at Marvel Loch, near Southern Cross, is practically worked out, as the oxidized zone is depleted and the sulphide is too poor to pay. The Company's other mine, the Transvaal, is shut down, as no known process can treat the ore successfully, owing to the presence of abnormal quantities of arsenical pyrite in it. Anyone discovering an economical way of overcoming this difficulty would find a wide field for such a process in this state, as several otherwise promising mines have had to be abandoned owing to the presence of arsenic and copper in the ore.

Since it was proved, three years ago, that the Great Boulder main lode had reëntered the Golden Horse-Shoe ground, the main shaft of the latter has been sunk 700 ft., and levels opened up at 2480, 2630, 2780, and 2900 ft. At each of these levels, at or near where the lode was penetrated by cross-cutting, free gold and telluride are showing, and assays are abnormal. At 2480 ft. the lode assays $306 per ton for 48 in., and at 2900 ft., where it has just been cut, the lode is 15 ft. wide and worth $18.36 per ton. In addition to these developments, a practically new mine is being opened up in the southern section of the lease. This section was worthless down to 1200 ft., but below that the ore-shoot has gradually lengthened and proved profitable as far as Chaffers boundary, 1100 ft. south of the main shaft, or 600 ft. farther than in the upper levels. The ore in this section is much richer than has been milled during the past three or four years, and bids well for the future of the mine. At No. 14 level the last 200 ft. of No. 3 lode before reaching Chaffers boundary assays $26.52 per ton for the full width of the drift. At No. 18 level No. 3 lode from 500 to 800 ft. south of the main shaft assays $15.30 over a width of 6 ft., and good values still continue south. Owing to these developments, No. 2 shaft, 730 ft. south of the main shaft, which was only 1291 ft. on December 31, 1911, reached 1552 ft. on that date in 1912, 1879 ft. at the end of 1913, and 1924 ft. shortly after. Next year's returns from the mill should show a considerable improvement.

Ore reserves of the Ivanhoe mine at Kalgoorlie on June 30 totaled 986,873 tons averaging $9.10 per ton. In the September issue of the *Monthly Journal* of the Chamber of Mines, L. R. Benjamin discusses the subject 'Dissolved Gold in Slime Residue.' The assay using cuprous chloride is described.

The gold output of the state in August totaled $2,175,800, and dividends $206,500, making the total to date $591,674,600 and $123,639,800 respectively.

NEW YORK

BUTTE & SUPERIOR EARNINGS.—PORCUPINE MILLS.—CYANIDE MANUFACTURE.—COBALT COMPANIES.—SCHEME TO SELL COPPER IN EUROPE.

The Butte & Superior Copper Co., which does not produce any copper, but does produce large amounts of zinc, shows in its report for the third quarter of the year, as published on page 861 of this issue, that the estimated net earnings for 1914 will be $1,265,000, or $4.75, against $3.50 per share last year.

Gold mining companies at Porcupine continue to increase their output. The Hollinger is adding another 40 stamps to the 60 now at work, and the Dome is also increasing its capacity through changes in the mill practice. Shipments of cyanide have been received, and P. A. Robbins of the Hollinger is quoted as saying that there is now enough in the district to last a year.

The American Cyanamid Co. has secured the machinery which it ordered in Germany some time ago and will at once proceed to manufacture low-grade cyanide, or surrogate, at its plant on the Canadian shore of Niagara Falls. There are not sufficient quantities of this material yet available in this country to make a conclusive test as to whether it will be satisfactory for cyanide work, but several of the large users have made arrangements to test it as soon as it can be supplied. One shipment of cyanide has come through from Germany to New York, but it is not yet certain that regular shipments can be depended on.

The announcement that the Crown Reserve would cut its dividend to 3c. per share after December 1 caused a sharp decline in the quotations. Crown Reserve did not benefit as much as some of the other companies through the draining of Kerr lake, since it was found that at that point there was a thick layer of mud on the lake bottom, and no prospecting can be done without deep trenching.——It is reported that Mr. Hay, president of the Trethewey, and Mr. Rogers, superintendent of the Coniagas, have agreed to serve on the board of directors of the reorganized Bailey Cobalt, and good progress is being made in straightening out an unpleasant situation.

Last week a representative of Henry R. Merton & Co., who had been in this country on a mysterious mission, returned to London, and it is now reported that the arrangement he had been trying to make was for his firm to act as the general sales agent for American copper in Europe. As Great Britain is already exhibiting an undesirable amount of control over shipments from this country, the scheme naturally met with but little favor, and he was obliged to return without accomplishing anything.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Fairbanks

Reports differ somewhat regarding the new gold discovery in the Tolovana district. One party returning to Fairbanks stated that the original stakers had not reached bedrock on November 2. Some prospects were good. Others state that the area may prove to be a fair producer, but only as a dredging district.

Samples of quartz containing gold, silver, copper, antimony, lead, and pyrite, gathered from 60 different properties in the district, have been on view in Fairbanks before shipment to the Panama-Pacific Exposition at San Francisco.

Juneau

Dividends of 20c., $1, and 20c. per share respectively will be paid by the Alaska Mexican, Treadwell, and United companies on November 28. October returns from the first two mines were as follows:

Results.	Alaska Mexican.	Alaska Treadwell.
Development, feet	108	701
Stock of broken ore, tons	—2,329	—44,155
Stamps working	120	540
Ore crushed, tons	19,705	79,233
Concentrate treated, tons	403	1,769
Total realizable value of gold	$45,391	$154,742
Yield per ton	2.33	1.97
Operating expenses	25,252	83,844
Construction expenses	6,368	21,833
Estimated net profit	13,771	49,065

Valdez

Two weeks' run at the Granite mill recently yielded gold worth $13,000. The mine is opening satisfactorily under the management of W. R. Millard.

ARIZONA

Greenlee County

The Arizona Copper Co. produced 2,694,720 lb. of metal in October.

Maricopa County

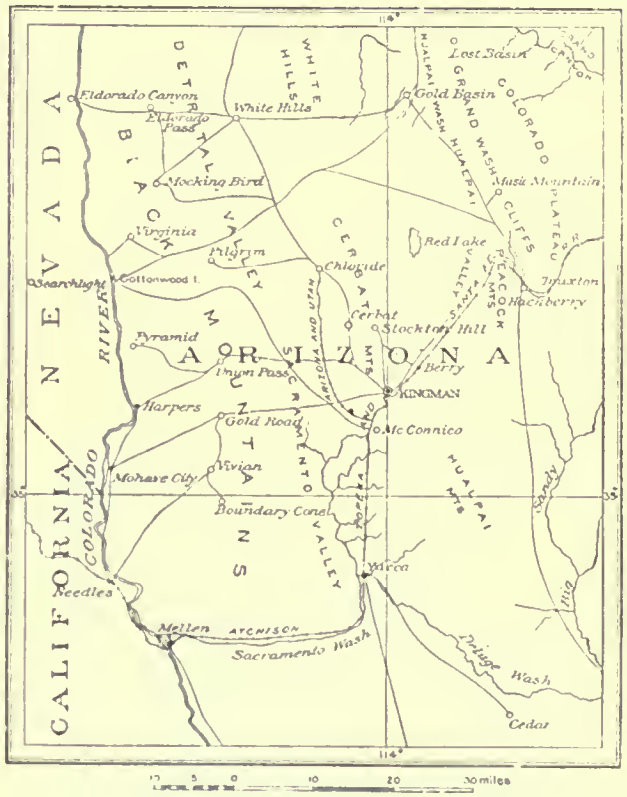
In a contest of first-aid and mine-rescue teams at Phoenix last week, results were as follows: first-aid, Old Dominion first and second, and Detroit third; helmet contest, Copper Queen, Detroit, and Old Dominion. The prizes won were as follows: Old Dominion, $150; Detroit, $150; and Copper Queen, $100 and a cup. U. S. Bureau of Mines and Arizona officials were in charge of the contests, which were considered very evenly matched.

Mohave County

At 500 ft. in the Gold Road mine, in the east end, 4 ft. of high-grade ore has been opened. D. R. Muir is manager.——A winze from the 900-ft. level of the Tennessee is down 160 ft. ——Four feet of ore assaying 4.5% zinc has been cut in the Golconda mine.——Los Angeles officials of the Tom Reed have been visiting the property.

Yavapai County

A syndicate headed by W. S. Wilhelm, of Long Beach, California, has secured control of the New State claims in the Hassayampa district. Some good gold ore has been opened in the Shamrock claim. A mill containing Nissen stamps and cyanide plant is to be erected.——Development in the Emporia and Yellow Jacket mines, near Prescott, is so satisfactory that a 5-stamp mill will be installed in the former.



MOHAVE COUNTY MINING DISTRICTS, ARIZONA.

CALIFORNIA

The oil output of the state in October was 282,152 bbl. per day, a decrease of 8000 bbl. compared with September. Shipments from the field totaled 7,749,136 bbl., and the surplus at the end of the month was 56,024,899 barrels.

The University of California announces that at the recent state elections it was decided by a majority of over 140,000 to issue bonds amounting to $1,800,000 for construction of new buildings on the campus. Work will be started early in 1915, steel and stone to be used in construction.

Amador County

The Plymouth gold output in October was $44,100 from 9000 tons of ore.

Butte County

An old gravel mine on Big Kinshew creek, near Ramsay Bar, is to be worked this winter by H. B. Scott, J. Proctor, G. La Febre, and J. Jenson.

Imperial County

(Special Correspondence.)—During the second week of November a cloudburst broke near the Imperial Reduction Co.'s property at Ogilby, and water flowed through an abandoned portion and completely filled the present workings of the mine. The oxidized ores of this American Girl mine were worked years ago, and many of the old workings do not show on the

old inaccurate maps. There was not much rain in the immediate vicinity of the mine, as the heavy fall of water occurred at the head of a gulch which crosses the vein near its mouth. This big rush of water broke through into an old caved stope which did not show on the surface, and poured into the mine for about three hours, there being no way to stop it. This came on through the No. 3 level to the incline shaft, down which it poured so the men barely had time to escape from the lower level. The shaft is now caved in slightly below the water-level, and the superintendent's report states that about four months will be required to unwater the mine and open the shaft. These dry desert mines are not prepared to handle quantities of water on short notice, so a special 75-cu. ft. water-skip was built in Los Angeles and shipped to the mine, so that the work of unwatering will soon start with three shifts. In the meantime all other work had to stop, and the mill was closed down. The damage to the mine cannot be estimated until the water is out. As it was a dry mine, with a 'ravely' hanging, and dry clay seams on the foot-wall, much caving can be expected, so six months work can be reckoned on before the mine is in shape to start the mill. This is not the only damage in a case of this kind.

Pasadena, November 21.

NEVADA COUNTY

Four miles below Grass Valley is the Deadman Flat district, an increased activity is noticeable of late. Work has been resumed at the Gold Mound, West Point, and California claims, and when litigation is completed, the Kenosha will be reopened.

The Whiskey vein of the Golden Center of Grass Valley, which has yielded $17,000 from 5000 tons at 500 ft., shows 16 in. of ore on the 700-ft. level. Good returns are expected from this shoot. At 500 ft. depth, the north drift is in 375 ft., and within 60 ft. of the Garage vein. In order to cope with water, another pump of 500-gal. capacity has been ordered. The present flow is 340 gal. per minute. So far this Company has spent $125,222 in the mine and equipment.——Between the Brunswick and Empire mines is the Le Duc, and after driving 3000 ft., and cutting two veins, $12 to $50 ore containing galena and other minerals has been opened.

PLUMAS COUNTY

As soon as litigation between the owners of the well known Droege mine and others in the district is settled, there is a chance of extensive development being done and the 25-stamp mill started.

SHASTA COUNTY

Fifty tons of ore and minerals is ready at the Redding railway station to be forwarded to the Panama-Pacific Exposition, and five tons for the fair at San Diego. M. E. Dittmar is in charge of the collection.

Curtailment of copper production has stimulated prospecting and working old gold producers in this county. San Francisco people have reopened the Niagara near French Gulch, with Jesse Peters in charge.——The Midas mine, at Harrison gulch, has been unwatered after several months' work. The mill and cyanide plant are working, and 60 men are employed on the property. The Gladstone shaft is being sunk and 20 stamps are working.——Six feet of ore is showing in the American.

SISKIYOU COUNTY

(Special Correspondence.)—A 5-ft. shoot of $50 to $200 ore has been opened in the Homestake mine, Salmon River district. Specimens are on display in Yreka. The Homestake is owned by R. S. Taylor of Yreka.——The small prospecting mill recently installed at the Big Cliff mine is running on rich ore. Development of a large body of mill ore is under way, and a larger mill may be installed next spring. H. B. Wintering is superintendent.——A small force is working at the Highland, under the management of John Mattern.——The Siskiyou Syndicate is vigorously prosecuting work at its Cub Bear and Blue Jeans mines. At the Blue Jeans, on Russian creek, an adit is being extended on a large vein of mill ore, 6 to 30 in. of which contains rich quartz. Several shoots of good ore have been uncovered lately at the Cub Bear, on Cow creek. About 500 tons of ore are on the dump, and arrangements have been made for steady work all winter. The management contemplates installing a mill next summer. Charles Ritz is superintendent.——The Siskiyou Mines Co. is working two giants at the Williams Point placer property, and is handling good gravel. Sufficient water is available for a long run. H. W. Payne is superintendent.——The Highland quartz mine, in the Trail Creek field, has been purchased from the Denny-Bar Co. by John F. Bellman, of Oakland, and Richard Werst, of Trail Creek. The mill is being moved to a more convenient point, and a sawmill will be erected in the spring. The property has been a good producer.

Yreka, November 9.

The Victor Mining Co., of Los Angeles, is prospecting its claims on south Russian creek.——Rich ore has been cut in the Hickey mine by the lessees, Meand and Nellon. A mill is in operation.

SONOMA COUNTY

A graphite deposit has been discovered near Healdsburg.

TRINITY COUNTY

A mill is being erected at the old Democrat mine, three miles from Weaverville, by E. E. Harrigan.

COLORADO

LAKE COUNTY (LEADVILLE)

There is generally a shortage of ore cars during the winter in the district, but this will not happen this season, as the D. & R. G. railroad has added a long sliding at the Ibex and Garbutt properties, with room enough to hold 50 cars.—Rich gold ore continues to be mined from the Jonny claim.——The outlook of the Twin Lakes and Lackawanna districts is good, and three properties are yielding high-grade ore.——The Lake Park area is attracting attention again by reason of lessees opening rich gold ore in an adit of the Laplander.

SUMMIT COUNTY

Gold sent to the Denver mint from the Breckenridge dredging companies, during the first three days of November, was worth $63,000. This was part of the October clean-up from the Tonopah placers and French Gulch ground.

TELLER COUNTY (CRIPPLE CREEK)

Three carloads, or over 100 tons, per week of ore is being shipped from the El Paso dumps by the lessee, John Sharpe. Concentrators are being installed to handle the poorer material, when the output will be considerably increased.

The 150-ton mill and cyanide plant for the Cripple Creek Cyanide Milling & Mining Co. will be built by the Colorado Iron Works of Denver. The cost is estimated at $70,500.

IDAHO

SHOSHONE COUNTY

The Sunset mine at Wallace was inspected by W. A. Clark, of Montana, two weeks ago. Large reserves of low-grade ore have been opened. Tests on the ore are being made in the new Elm Orlu mine at Butte, Montana. Eight feet of 40% zinc ore is showing in the silver table mine, east of Mullan.

The annual meeting of the Hypotheek Mining & Milling Co. was held at Wallace on November 17. The new shaft is 900 ft. deep, and the vein should be cut 85 ft. from the station just finished. Arrangements have been made to secure a millsite and right-of-way for a tramway from the mine.

In a rise in the Black Bear mine near Wallace there is 7 ft. of ore which assays up to 59% zinc, there being also some lead ore in the rise. According to the manager, Peter Bernier, a mill will be erected next spring.——In the Coeur d'Alene

company's claims, adjoining the Silver Cable, above Mullan, lead-silver ore is being opened.——Development in the Sonora is quite encouraging as the deeper ground is opened.

MICHIGAN

HOUGHTON COUNTY

The Superior mine compressor house was burned on November 16. Boilers and other machinery were not damaged much. A blizzard was blowing at the time. The plant will be reconstructed and the mine closed for about a month.

The Mutual Line steamer *North Sea* is loading 5300 tons of copper at Lake Linden, or 600 tons more than that taken by the *North Star* last week. This cargo is worth about $1,245,000. The *North Lake* will load about 4000 tons of metal on November 30. The total movement for the season will amount to about 35,000 tons.

MISSOURI

JASPER COUNTY

In anticipation of better prices for their products, operators in the Missouri-Kansas-Oklahoma district are more active of late in prospecting by drilling and by other methods. Instances are the Lone Elm Development Co.'s claims northwest of Joplin, Rex Mining & Smelting Co. east of Joplin, the Continental Zinc Co., Twin Cities Mining Co., Granby Mining & Smelting Co., and the Cornfield Mining Co., at Miami, Oklahoma.

The American Zinc, Lead & Smelting Co. has ordered several water drills for use in its No. 3 mine at Carterville. This action results from the agitation against dust in the mines, while inspection of the district mines was started last week by E. Higgins, an engineer with the U. S. Bureau of Mines; A. J. Lanza, of the U. S. Public Health Service; and deputy mine inspectors, W. W. Holmes of Webb City, I. L. Burch of Joplin, and C. M. Harlan of Carterville. They are assisted by officials of the various cities in which mining operations are conducted and by officers of the Jasper County Tuberculosis Society.

MONTANA

SILVERBOW COUNTY

According to W. A. Clark, interviewed at Salt Lake City, the Timber Butte mill at Butte is giving excellent results. The recovery is over 93% and the concentrate averages 52% zinc. The suit between the Elm Orlu and Butte & Superior is to be heard on January 28, 1915, and Mr. Clark states that the orebodies are being studied by engineers for both sides.——In spite of difficulties in the Butte & Superior main shaft, retimbering is proceeding at a satisfactory rate. Four shifts of six hours each are employed, eight-hour wages being paid. Some changes are being made in the flotation plant in the mill.

NEVADA

The University of Nevada is discussing the problem of extending its work and opening about six schools of mines in the state, one of which would be at Tonopah, if the necessary legislation and money is obtainable.

ELKO COUNTY

At a depth of 77 ft. in the Flaxie mine at Jarbidge, high-grade gold ore has been cut. There is said to be 250,000 tons of ore blocked out throughout the mine.——A 10-stamp mill is to be erected on the Bluster mine nearby. Also a 3500-ft. tramway and a sawmill of 5000-ft. capacity per day. The mine shows from 40,000 to 50,000 tons of ore. The General Engineering Co. of Salt Lake City states that 70 to 80% of the gold is recoverable by amalgamation. T. B. Beele is president at Salt Lake City.

ESMERALDA COUNTY

A meeting of the Goldfield Merger Mines Co. was held at Goldfield on November 20. Future operations of the Company largely depend on results obtained by the Atlanta in proving the 1750-ft. level. The new pumps in the Merger are now working well. A. I. D'Arcy is general manager of both properties.——Developments in the Silver Pick are quite encouraging of late.——A 150-ft. winze is to be sunk from 700 ft. in the Keewenas, near the boundary of one of the Consolidated claims.——At the New Jersey mine, in the eastern part of the field, the main shaft is down 490 ft. It is to be sunk to 600 ft. At 400 ft., 500 ft. of work has been done, and 4 ft. of $5 ore cut. Harry Ernest is in charge.——Great interest centres in development in the Jumbo Extension.

Final returns of the Goldfield Consolidated mine for October are as follows, according to the assistant general manager, K. M. Simpson: mine development, 2874 ft. at a cost of $6.02 per foot; ore treated, 28,651 tons; net realization, $149,373; total costs, $6.66 per ton; lessees output, 1209 tons worth $20,262, of which the Company received $10,882, less transport and milling. In the Combination mine the 230-ft. level 292 Z sill was extended, and produced 275 tons of $53 ore. The M X sill at 245 ft. in the Mohawk gave 70 tons of $28 ore.

NYE COUNTY

Eight mines at Tonopah produced 46,954 tons of ore worth a total of $821,695 during October. The output last week was 10,428 tons valued at $203,664.——The Montana mill closed on November 21 for about 90 days.——A new melting furnace for gold precipitate is on its way to the Extension mill from the East. The West End Consolidated shipped 29 bars of silver, weighing 43,485 oz., on November 19.

WHOLESALE PRODUCTION OF SILVER AT TONOPAH. BULLION FROM THE WEST END MINE, 48,105 OZ. VALUED AT $35,581.

During the year ended September 30, the Jim Butler Tono-

pah Mining Co. produced 34,722 tons of ore valued at $744,799. or $21.45 per ton. The profit was $247,500, or $7.13 per ton, giving a cost of $12.18 per ton. The cash position at the end of the year was $185,780, loans on collateral, $230,780, and a large quantity of silver, making total cash resources of $325,-000. Ore reserves consist of 33,000 tons blocked on four sides, also ore worth $500,000 in ground in dispute between the Company and the West End Consolidated.

The Round Mountain Mining Co., at Round Mountain, to operate its placer ground, is proceeding with the construction of a ditch. There will also be eight miles of pipe, costing about $50,000, the whole scheme to cost between $125,000 and $150,000. No contract has yet been let for the pipe. Ore worth from $20 to $40 per ton has been opened on the 800-ft. level of the mine. The main shaft is down 950 ft., showing $3 to $9 ore. James R. Davis is president.

At Manhattan, the Monitor-Belmont Mining Co. has ordered an all-sliming cyanide plant of 150-ton capacity. It will consist of the following: Blake jaw-crusher, ten 1550-lb. stamps, two 5 by 18-ft. tube-mills, and Dorr classifiers, thickeners, agitators, and continuous decantation, supplied by the Allis-Chalmers company.

UTAH

Utah mining men met in Salt Lake City last week to consider the scheme of sending a large delegation to the American Mining Congress at Phoenix, Arizona, on December 7 to 11. It is intended to try to have the 1915 meeting held at the Utah capital, also to make that city the permanent headquarters of the congress.

Beaver County

Placer land amounting to about 4000 acres is being transferred to a company backed by A. B. Shedd, W. D. Washburn, and C. C. Chapin of Chicago. Tests of the ground average $1 per cubic yard. Other large areas have been located, and Frederick Porter of Chicago has a three-year option on some claims for $100,000.

Juab County

The 1700-ft. level drift of the Eagle & Blue Bell has been started, and to reach the ore, about 300 ft. will have to be driven. The daily output is from 75 to 100 tons.——At the Yankee Consolidated, work during the current year has been mostly at 1700 ft. At 2000 ft. east of the shaft 12 to 40 ft. of quartz formation was opened by a rise to 230 ft. above this level, assaying 1 to 4% lead, 2 to 16 oz. silver, and some gold. It improves in value as development proceeds. Other prospecting is encouraging.

A statement of the situation of the Knight properties shows that the Iron Blossom company has a surplus of about $300,000; Colorado, $86,000; and Beck Tunnel, $27,000. Diamond-drilling is to be done from the 1900-ft. level of the Iron Blossom.——Twenty-six lessees are working in the Eureka Hill mine, in charge of the superintendent, Charles Baker.——The Utah Power Co. is making extensive improvements in Tintic.

Salt Lake County

The Ohio Copper Co.'s affairs are still the subject of considerable discussion. George Baglin, former general office manager of the Company, states that the property is being prepared for sale instead of reorganization, and labor claims for $110,000, as published, are less, being only $37,790. Supplies at the mine and mill are worth $56,099, and on September 17 there was on equity in copper with the American Smelting & Refining Co. on 3,872,475 lb. of metal, on which the advances, smelting, and other charges totaled nearly 8c. per pound, so the Company's equity would be whatever the copper was sold for in excess of this amount, which would be greatly in excess of the obligations of the Company.

Utah County

A rock asphalt deposit is being mined by J. W. Mellen at Thistle, south of Salt Lake City, the product used in paving streets in the latter city. The daily output is 75 tons, the material being extracted by adits. George Fuerman is superintendent of the mine.

WASHINGTON

Okanogan County

A 50-ton mill and other equipment, costing $25,000, are to be erected by the Rich Bar and Golden King companies at Oroville, according to J. W. Douglas of the former. Both properties are opening satisfactorily and others are promising.

Stevens County

A 4-drill compressor, 85-hp. boiler, 25-hp. mine hoist, and lighting system have been sent to the Hecla mine at Chewelah, controlled by Spokane people. Fred F. Foster is manager.

CANADA

Ontario

A three months' extension of time, from August 15 to November 15, in which to do assessment work was granted by the minister of lands, forests, and mines, and another six months' extension, to April 15, 1915, has also been allowed.

The Dominion Steel Corporation reports for the six months ended September 30 as follows: net earnings, $2,106,771; sinking funds, etc., $484,705; interest, etc., $927,981; preferred dividend, $210,000; preferred dividend on coal company, $105,000; surplus, $379,084; surplus on April 1, $796,907; and total surplus, $1,175,991.

The Dome mill in October treated 22,500 tons of ore averaging $4.70 per ton. This is the largest tonnage for a month.——It is expected that the McKinley-Darragh company will exercise its option on the Jupiter mine, as development has been satisfactory. Work is concentrated on the vein on the 400 and 475-ft. levels.

The Seneca vein in the Cart Lake lease has yielded about 125,000 oz. of silver, and has paid for the mine's development. The shoot is practically worked out. Six tons of 2000-oz. ore was extracted from the 335-ft. stope last week, and sent to the Nipissing mill.——The Seneca Superior company will pay a 10% dividend, equal to $47,638, on December 15. The total since 1913 is 135% and $643,218.

The Department of Mines of Ontario has published the following data covering nine months of 1914: gold, 196,934 oz.; silver, 19,448,018 oz.; copper, 11,585 tons; nickel, 18,085 tons; iron ore, 165,759 tons; pig iron, 495,161 tons; cobalt, 95 tons; and cobalt and nickel oxide, 852,014 pounds.

MEXICO

Sonora

At Nacozari the 2000-ton mill of the Moctezuma Copper Co.

MOCTEZUMA MILL, NACOZARI, SONORA.

is treating about 1600 tons per day. Experiments on flotation processes are being made.

PHILIPPINE ISLANDS

In *The Philippine Journal of Science* for June is a paper on 'The Iron Ores of Bulacan Province,' by F. A. Dalburg and Wallace E. Pratt. It is accompanied by one map, six plates, and six test figures. Besides the authors, some field work was done by Warren D. Smith and Feliciano Nable. The work was to make a study of the geology of the ore deposits, their extent, factors affecting mining and smelting, and the native smelting processes, with a view to improvement and expansion. The field work was very difficult on account of the heavily wooded, mountainous, and almost impassable region, and a lack of an accurate map. In their summary, the authors state that the ores are situated on the edge of the eastern cordillera of Luzon. The orebodies are not continuous, but are at intervals of about 15 kilometres (9 miles). They occur at the base of the Miocene sedimentary rocks. Intrusive rocks in the form of dikes are found in proximity to the deposits. The ores consist of magnetite and hematite in intimate mixture, quartz being the most abundant gangue mineral, while pyrite is common. Those mined at present average over 60% iron, and sulphur and phosphorus are not too high. There is probably over 1,000,000 tons in sight, but definite estimates could be made at little cost for exploration. Filipinos mine and smelt the ore at present for

TYPICAL FOREST-COVERED SLOPE IN IRON ORE REGION, MT. MAYAPO, PHILIPPINE ISLANDS.

agricultural implements. The industry dates back to 1664. These ores might be exploited on a larger scale by electric smelting, hydro-electric power, charcoal, and fluxes being available. The situation of the deposits in a difficultly accessible region makes them less readily available than other known ores in the Philippines. The smelting practice obtaining is fully described, and in 1913 there was 55 tons of ore treated, yielding 227 tons of cast iron. The output since 1664 is estimated as 13,960 tons of ore for 4617 tons of iron worth ₱754,949.

During October, two boats of the Philippine Dredges, Ltd., recovered 736 oz. gold, and one boat 39 oz. The latter was stopped for repairs to a boiler. No. 4 has started work.

THE ENGINEERING DEPARTMENT of the University of Idaho, at Moscow, entertained mining men of the Northwest on November 21. Co-operation in university research was discussed.

THE ILLUMINATING ENGINEERING SOCIETY, Chicago branch, met on November 24, when S. E. Doane gave an address on 'Electric Light—A Factor in Civilization.'

THE UNIVERSITY OF WASHINGTON COLLEGE OF MINES' quarterly *Bulletin* gives details of the faculty, courses, and other information for the 1914-15 year.

THE MACKAY SCHOOL OF MINES OF THE UNIVERSITY OF NEVADA has just added a Sperry filter-press and accessories to its cyanide plant.

PERSONAL

E. B. KIRBY is in New York.

S. H. BALL is back in New York.

H. C. BELLENGER is at Rancagua, Chile.

F. J. DENNIS has returned to San Francisco.

J. F. CALLBREATH has returned to Washington.

HENNEN JENNINGS was in New York last week.

E. P. MATHEWSON has been in San Francisco this week.

T. T. READ visited Baltimore and Washington this week.

D. C. JACKLING was in San Francisco last week and has gone to Ely.

THOMAS NORTON TURNER has returned to San Francisco from Nikolaievsk.

WILLIAM A. PRICHARD was in New York and will sail for London on November 28.

W. SPENCER HUTCHINSON has been studying the Sunflower quicksilver district of Arizona.

A. M. WALSH has recently taken charge of the Pioneer Gold Co.'s mines at Towle, Placer county, California.

R. B. LAMB has returned from Renfrew county, Ontario, after examining molybdenite deposits, and is now in Cobalt.

R. H. ERNEST, superintendent of the Round Mountain Mining Co., with headquarters at Round Mountain, is at Goldfield.

GEORGE A. GUESS was in New York recently, returning from Anyox, British Columbia, where he has been studying metallurgical problems.

ROBERT STIGHT is in New York, and will speak before the New York section of the American Institute of Mining Engineers on December 2.

H. W. TURNER is expected in San Francisco before Christmas. When last heard from he was bound for London by way of Petrograd and Norway.

E. S. BARDWELL will be in San Francisco for the next year in connection with the exhibit of the Anaconda company at the Panama-Pacific International Exposition.

BERNARD MACDONALD is at Tombstone, Arizona, conducting experimental work in cyanidation on the ores of the mines recently purchased by Phelps, Dodge & Company.

JOHN A. SCHROEDER has resigned as general sales manager for the Hyatt Roller Bearing Co. of Chicago, Detroit, and Newark. His successor has not yet been appointed.

JAMES S. DOUGLAS has resigned as general manager for the Greene Cananea Copper Co. and it is understood that the active management of the property will again be under the direction of L. D. RICKETTS at the first of the year, when it is stated, operations at the property will be resumed.

Obituary

JAMES RAY WHIPPLE, who died of abdominal cancer, November 7, was one of those men who had in a peculiar degree the faculty of winning the affections of men. He was a famous football player while a student in the University of California, and a teammate of B. L. Thane, with whom he was later associated in mining in Alaska. Born in Alameda county, California, in 1873, he was educated in his native state and went from there to Alaska, where his whole professional career was passed. At the Eagle River and Kensington mines he showed marked ability, and it was natural that when Mr. Thane took hold of the Alaska Gastineau, Whipple should be made his assistant. He was an important factor in the rapid merging of individuals into a staff that was necessary in the work since accomplished at Juneau, and his death is keenly regretted.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

LOCAL METAL PRICES

San Francisco, November 25.

Antimony	15 —15¾
Electrolytic copper	13 —13¼
Pig lead	4.15—5.10
Quicksilver (flask)	$55
Tin	34½—36
Spelter	6½— 6¾
Zinc dust, 100-kg. zinc-lined cases	10

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, November 25.—Prices today are as follows: copper, strong at 12.25 to 12.50c.; lead, firm at 3 90c.; and spelter, quiet at 5.10c. per pound.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59 32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58 52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

The silver market has been steady and stronger during the past week. Prices were as follows: New York, 49.50, 49 12, 49, 48.87, and 49.37c.; and London, 22.87, 22.75, 22.62, and 22.81d. per ounce. The steamer 'Siberia' took silver worth $97,413 (say 200,000 oz.) to the Orient on November 21. Metal is being stored at many silver-producing centres. As an instance of this, the Jim Butler company of Tonopah had 275,456 oz. on hand on October 1, according to its annual report just published. In discussing the recent slump in silver prices, Samuel Montagu & Co. of London states that the regular decline was checked by a cessation of sales from America. This happened to coincide with a recrudescence of buying orders from the Indian Bazaars, which came on a limited market, making a sharp rise. A temporary contraction of supplies, however, only imparts artificial strength; it does not create a market. To be galvanized into life, the market requires a continuous and substantial revival of Eastern demand. The shortage of exports to the East, up to November 5, compared with last year is £5,032,000, or say 50,000,000 oz. This explains the heaviness of the market. Crops in South Manchuria have been poor, and the purchasing power of the Chinese is greatly lessened.

COPPER

Prices of electrolytic in New York, in cents per pound.

Average week ending

Nov. 19.....11.75 Nov. 25.....12.25 to 12.50

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	16 54	14.21	July	14.21	13.26
Feb.	14.93	14.46	Aug.	15.42	12.34
Mch.	14.72	14.11	Sept.	16.23	12.02

May	15.42	13.97	Nov.	15.08	....
June	14.71	13.60	Dec.	14.25	....

Buying was stronger last week, and the reduced output of the metal is now visible in refinery outputs. The price advanced throughout the week, being 12.50c. at the close. Export demand from England and France was good; and some orders from Italy have been booked, though no arrangements are ready for sending copper forward to that country. According to Henry R. Merton & Co., of London, European visible supplies on October 31 totaled 36,566 tons, an increase of 1972 tons. On November 15 these amounted to 30,482 tons. The average for electro in October was £53 3s. 5d. per ton, or 11.39c. per pound. Present prices are £58 5s. per ton. The Sulitjelma mine in Norway produced 1785 tons of copper concentrate in October.

CYANIDE

An interesting note on this salt appears in the New York letter of this issue.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Monthly averages.

June	4.33	3.90	Dec.	4 02	....

Lead is firm at St. Louis at 3.80 to 3.82½c. per pound. London, £19 5s. per ton. Spot lead has commanded a good premium in England, owing to Russian demand absorbing stocks available for immediate shipment. The average price in October was £17 9s. 10.6d. per ton.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slighly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb, are given below:

Monthly averages.

Week ending			
Oct. 29	50.00	Nov. 12	55.00
Nov. 5	55.00	" 19	55.00
		" 25	55.00

Monthly averages.

May	49.10	33.29	Nov.	39.77	....
June	45.10	30.72	Dec.	37.57	....

A good deal of business has been done in this metal, and wholesale lots are about 32.60c. per pound. Up to November 20, arrivals of tin in New York totaled 1395 tons, and a further 2580 tons was due by the last day of the month. London prices are £138 10s. to £140 per ton. Tin mills in West Virginia have been resuming work lately.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Monthly averages.

Spelter is firm at St. Louis at 5.15c. per pound. London, £25 5s. per ton. The English market has been quiet. Average price for October was £23 13s.6.3d. per ton.

COMPANY REPORTS

BUTTE & SUPERIOR COPPER COMPANY, LTD.

The third quarterly report of this great zinc producer at Butte, Montana, shows the following results:

Details of operation.	Third quarter of 1914.	Second quarter of 1914.
Development, feet	5,309	4,885
Ore milled, tons	100,600	95,500
Average zinc content, per cent	18.582	18.282
Average silver content, oz. per ton	8.636	9.847
Concentrate produced, pounds	60,974,968	57,824,296
Average zinc content, per cent	54.32	53.24
Average silver content, oz. per ton	24.15	26.36
Metal in concentrate, pounds	33,121,312	30,786,658
Extraction, per cent	89.14	88.17
Cost of mining, per ton	$3.201	$3.138
Cost of milling, per ton	$2.049	$2.023
Net value of all products, etc.	$1,027,576	$805,866
Profits, including metal inventories, $50,000 and $60,000	$554,136	$372,984
Average price of spelter, cents per lb.	5.11	4.94

After paying the quarterly dividend of 75c. per share the cash on hand at the end of the quarter was $808,761, and the net current and working assets, including products in transit, $1,327,153. The mine and mill are at present closed, owing to repairs to the main shaft between the 300 and 700-ft. levels, as has been mentioned in the *Press* of a previous issue.

MASCOT COPPER COMPANY

This Company operates at Dos Cabezos, in Cochise county, Arizona, and the report of the general superintendent, F. L. Sizer, to the general manager, Charles V. Weston, covers the year ended September 30, 1914.

Development in the mine totaled 4681 ft., also 662 ft. assessment work on unpatented claims. With a reduced force, the past six months has averaged 500 ft. per month underground. Diamond-drilling amounted to 8019 ft. at $2.11 per foot. Twenty-six holes were drilled, of which eleven cut vein formation or ore, and showed the proper direction for drifts and cross-cuts which opened large orebodies. Only one drill was worked during the past seven months.

The Iron Tower orebody has been blocked out for a vertical height of 280 ft. above and below the 200-ft. level, and on four different levels. It is estimated that there is 500,000 tons of ore in this shoot, and additional ore should be proved above the 100-ft. level. This level has been connected with the Oregon shaft, and from this level rises will be driven to the limit of the sulphide ore zone. Levels from these rises will determine the lateral extent of the orebody.

No. 1 and 2 shafts were sunk from the Consolidated adit late in January, since which time work has been done at 600 and 800 ft. resulting in the following discovery: From the 600 and 800-ft. levels, besides opening ore, suitable stations will be available for diamond-drilling. Water-level should be near the 800-ft. level. The total ore reserves are estimated at about 750,000 tons, and before long the mine will be able to produce 100 tons per day, to be increased shortly after to 200 tons. Improvements to equipment include 900 ft. of 4-in. air-pipe, and a large hoist and pump for No. 2 shaft. On the 600-ft. level of No. 2 shaft, No. 1 vein was cut, showing 10 ft. of mixed chalcopyrite and bornite assaying 9.6% copper and $3 per ton in gold and silver, also 16 ft. of formation containing a little copper.

MINERAL STATISTICS

The production of metals and metallic ores in 1912 and 1913, as compiled by J. P. Dunlop, has been published by the U. S. Geological Survey. The following table shows the ores extracted from domestic mines during the past three years:

	Short tons.		
Ores.	1911.	1912.	1913.
Iron	46,023,540	63,859,728	66,800,270
Manganese	2,752	1,864	4,533
Manganiferous iron	3,006	3,247	10,808
Chromium	134	225	286
Tungsten	16,500	34,000	34,400
Titanium	.....	6,900	7,600
Aluminum	174,292	179,049	235,470
Gold	9,884,684	9,736,203	9,403,622
Silver	739,200	848,574	1,253,116
Quicksilver	138,525	155,693	136,278
Tin	42,200	3,000	7,500
Vanadium and uranium.	8,468	18,000	27,900
Antimony	.....	.....	116
Copper ores:			
Western states	18,207,566	23,431,301	28,427,543
Central states	10,978,827	11,411,941	7,016,831
Eastern states	801,842	830,089	892,308
Total	29,988,235	35,673,331	36,336,682
Copper-lead ores	6,923	14,614	24,399
Lead ores:			
Western states	2,157,817	2,388,598	2,563,904
Central states	3,794,712	4,064,366	4,250,800
Total	5,952,529	6,452,964	6,814,704
Zinc and zinc-lead ores:			
Western states	1,356,781	1,344,222	1,658,486
Central states	10,629,269	11,899,185	10,767,340
Eastern states	413,332	497,832	692,348
Total	12,399,382	13,741,239	13,118,174
Grand total	105,380,370	130,728,622	134,215,858

The total value of metals reduced from these ores in 1913 was $855,351,064, compared with $834,520,702 in 1912.

If the degree of activity of the building industry is taken as an index to prosperity, figures gathered by the Survey, of building operations in 1913, show that prosperity is sporadic. In 48 of the largest cities of the country, the total cost of building operations in 1913 was $659,515,746, compared with $738,989,710 in 1912. The greatest decrease was in New York City, $56,414,655. The largest increase was in Chicago, $6,492,527. New York City is the leading city in the cost of building operations, notwithstanding its large decrease in 1913. Last year the building operations of that city cost $107,104,707. The maximum annual cost of building operations in New York City was reached in 1909, when it was $186,047,477. Efforts were made to obtain detailed information for all cities of 35,000 or more inhabitants—157 in number. Information was obtained from 147 of these cities in sufficient detail to permit the compilation of statistics. In these building operations in 1913 cost $859,657,250. In 108 of these cities the new wooden buildings erected in 1913 cost $174,197,886 and new brick buildings cost $226,478,584. All other new buildings cost $115,894,022. The cost of all additions, alterations, and repairs was $78,483,933. New concrete buildings were reported by 71 cities, of which Philadelphia was the leader, reporting a cost of $4,634,855, and San Francisco was second, with $3,745,389.

RECENT PATENTS

1,114,055.—Metal Alloy. Edward Smith, London, England. A white metal alloy consisting of copper, 40; nickel, 8½; zinc, 5; tin, 2½; and lead, 1 part.

1,115,263.—Metallurgical Furnace. Utley Wedge, Ardmore, Pennsylvania. A metallurgical furnace having a central shaft and an outer casing, one rotatable in respect to the other, overlapping hearths carried respectively by said central shaft and outer casing, and rabbles depending from said hearths and serving to move the material over the same.

1,114,224.—Filter-Leaf. Newton A. Burgess, New York, N. Y., assignor to Butters Patent, Vacuum Filter Co., Inc., a corporation of Nevada. A filter-leaf comprising a frame, a filter medium mounted thereon and a pipe having a substantially straight portion adjacent to said medium and open at the bottom, said pipe being arranged so that the opening therein is beneath the surface of a cake formed on said medium.

1,115,531.—Apparatus for Grinding Ores and Other Materials. Harry W. Hardinge, New York, assignor to Hardinge Conical Mill Co., New York, a corporation of New York. In a mill for the purpose described, the combination with a drum provided with inlet and outlet openings, and means for rotating the drum about its longitudinal axis, of continuously operating automatic means for raising the outlet above the inlet opening and also lowering the former while the drum is revolving.

1,114,096.—Miner's Blasting Box. Joseph Benneck, Nanticoke, Pennsylvania. A blasting box, including a casing, a battery by the casing, wires forming a circuit connected to the battery, said circuit being broken at two points, a circuit closer adapted to close the circuit at one of said points, a lock having a bolt projectable to close the circuit at the other of said points, and said bolt acting as a conductor, and a key for operating the bolt, said key being withdrawable from the lock only in the open circuit position of the bolt.

1,114,935.—Process and Apparatus for Sizing or Classifying Comminuted Materials. Henry M. Sutton, Walter L. Steele, and Edwin G. Steele, Dallas, Texas. The process of sizing a mass of pulverulent material, consisting in feeding the material dry upon a continuously moving tranversely inclined roughened supporting surface, imparting to said mass an accelerated movement in the direction of its travel by gravity, causing the components of said mass to deviate from the line of normal movement contiguously at angles proportionate to their sizes, and separately collecting the sized particles.

1,114,036.—Metallurgy of Zinc. Augustin Leon Jean Queneau, Torresdale, Pennsylvania, assignor to Queneau Electric Zinc Furnace Co., Philadelphia, Pennsylvania, a corporation of Delaware. Extracting and recovering zinc from zinc ore, which consists in preheating said zinc ore, separately charging into a reducing furnace the ore in the preheated state and a reducing agent, intimately mixing them within the furnace, subjecting the mixture to a reducing atmosphere and a reducing temperature with exclusion of air, thereby releasing the zinc in the form of zinc vapor and condensing said vapor to the metallic state.

1,115,521 and 1,115,522.—Process of Extracting Copper from Carbonate and Oxide Ores. Henry R. Ellis, Salt Lake City, Utah. The process of extracting and recovering copper from its carbonate or oxide ores or from materials containing the carbonates or oxides of copper, which consists in subjecting such ores or materials to the action of a solution containing an alkaline carbonate or bicarbonate as described, separating the copper charged solution from such ores or materials and precipitating the copper from such solution by means of metallic lead; or by subjecting the same to the action of a cathode, consisting of mercury in combination with an insoluble anode.

1,113,323.—Treatment of Refractory Ores. John Foye, Henry Egbert Moore, and Robert Boyle, Johannesburg, Transvaal, South Africa, assignors to Refractory Ores, Ltd., Johannesburg. The process of treating refractory ore for the purpose of rendering it amenable to ordinary extraction methods, which consist in subjecting the ore in admixture with a solution of the salt of an alkaline metal which is substantially a non-solvent of gold, to the passage of an electric current, whereby the acid component of the solution separates in proximity to the ore and the alkaline component away therefrom, and subsequently separating the ore and solution.

MINING DECISIONS

Oil Lease—Improvements Made Under

Where lessees went into possession of oil land with actual notice of the adverse claims thereto of another, and, notwithstanding such knowledge, proceeded to expend considerable sums of money in boring wells and developing the property, they are not entitled to recover the value of such improvements made on the asserted ground even if they had made them in good faith without notice.

Loeb *v.* Conley (Kentucky), 169 Southwestern, 575. October 6, 1914.

Merchantable and Minable Coal

In an action on a contract for minimum royalty on coal not mined, where the contract provided that all 'merchantable and minable' coal should be mined, it was held that the defendant was entitled to show in defense of its contention that the coal left in the mine was neither 'merchantable nor minable' the condition of the coal, its distance from means of transportation, overhead and administrative charges, and the market price obtainable, as factors to be considered in arriving at the determination of the question.

Ellis *v.* Cricket Coal Co. (Iowa), 148 Northwestern, 887. September 30, 1914.

Coal Mining Lease—Construction

Where a corporation, which succeeded to the rights of the lessee in a coal mining lease, resisted a suit by the lessor for a forfeiture of the lease, obtained and acquiesced in a decree denying a forfeiture, referring the case to a master to compute the amount due the lessor under the terms of the lease and making it a lien, and continued to mine and remove coal for two years with as full knowledge as the lessor as to the conditions and extent of the coal underlying the property, and until it became hopelessly insolvent through no fault of the lessor or failure of the mine, it is estopped to ask a cancellation of the lease or an abatement of the bonus agreed to be paid for the mining right, on the alleged ground that the quantity of coal was misrepresented by the lessor.

Browning *v.* Boswell (Virginia), 215 Federal, 826. June 9, 1914.

New Machines and Devices

Small Stamp-Mills

The prospector and small mine operator in his efforts to mine at a profit in out of the way places has troubles which are real when handicapped by lack of funds for development work and elaborate milling equipment. To meet this requirement, miniature but practical milling plants have been designed which can be transported on mule-back, erected, operated, and moved to another locality if occasion demands, at small cost. The illustrations presented are of two such plants of the one-man variety which are being profitably operated. Both of the mills shown were made after patented designs of E. H. Moyle and supplied by the E. H. Moyle Engineering & Equipment Co. of Los Angeles. The mill shown in the left of the halftone is in the Wickenburg district of Arizona and will be seen to be not much larger than the operator.

TWO MINIATURE STAMP-MILLS OF THE 'ONE-MAN' VARIETY.

In the design of a miniature mill which will be both practical and efficient and at the same time cheap and easily transported, special construction is necessary in order that the mill may not shake to pieces and will crush fine a sufficient tonnage to make it a profitable investment. While the principle is the same as in the 1800-lb. stamp, there are many features which make it a distinct machine. The mills shown are one-stamp mills with steel frame, self contained, with an automatic ore-feeder attached, and are so simple in construction and operation that one man can operate them. One of the features of the miniature stamp-mill that is of special interest is the method of feeding the ore, it being fed by a patent arrangement on the entire periphery of the solid die as commonly used and not entering the mortar from one side as is the common practice. The ore is fed evenly around the stamp as the stamp rises, and the discharge is also on all sides of the stamp through the circular screens about the mortar. This is for the purpose of increasing the mill capacity and reducing the losses due to sliming. The frame, it will be seen, is of steel and carries both stamp and feeder. A heavy spring arrangement is fastened on the stem which materially accelerates the dropping force of the stamp. The stamp drops from 150 to 175 times per minute. High speed in the small mills has been found desirable from both a capacity and efficiency standpoint. Difficulty was experienced in the operation of the mill at Wickenburg due to the lack of water, which had to be hauled to the property at a cost of $1.50 per barrel. The operator has overcome this by collecting the surplus water and pumping it back with a small centrifugal pump which is driven by the 2-hp. engine which drives the mill. The ore treated is a hand-picked ore averaging $87, and the extraction inside the mill and on the plates is $79, while the operating expenses, except labor, total 65c. per day, including fuel for engine, shoes, dies, screens, and other expenses.

The illustration on the right of the halftone is of a portable mill of a larger size of the same design, which has been erected on a waste dump in San Diego county, California. The practice here is first to screen the material over a grizzly, after which the fine material is delivered to the automatic feeder of the mill, one man being easily able to operate this mill. The capacity of the mill crushing fine is from 4 to 8 tons per day. The construction of this mill is similar in every respect to that at Wickenburg and it was also built by the E. H. Moyle company.

The mills are especially designed for prospectors and operators of small means, as the total cost of the mill is most insignificant compared to the cost of the average mining plant. They have proved in many instances to be both practical and profitable for the small operator. They are also recommended as a help in enabling the owner of small means to raise funds for development work and a larger plant.

Commercial Paragraphs

Standard Gas Engine Co., San Francisco, California, has issued Catalogue No. 12, which is most attractively printed and devoted to the various products of this Company, which include marine, stationary, hoisting, and portable engines.

National Tube Co., Pittsburgh, Pennsylvania, is distributing a new folder descriptive of the Kewanee union. The following advantages are claimed for this union: one nipple, time required for making one less joint, one gasket, time required for cutting and fitting gasket, and cost of one malleable union, or in other words an average net saving of 16 cents.

Stevens Firearms & Tool Co., Chicopee Falls, Massachusetts, in Catalogue No. 53 describes in a general way with illustrations the different firearm products of this Company. The aim of the Company has been to present a catalogue that will concisely show the large line of sporting firearms and specifications of each model, and to eliminate lengthy descriptions and detailed information.

The Holt Manufacturing Co., Stockton, California, has published a catalogue devoted to the 'Baby Caterpillar' tractor machine manufactured by this Company. While the 'Baby' tractor is used largely for small farms, orchards, and vineyards, it also has a wide application in the field of hauling. The 'Baby' is a 30-hp. machine which is proving itself a valuable asset in various industries where heavy work is demanded.

Sullivan Machinery Co., Chicago, Illinois, has published Bulletin 58-M, which is devoted to the Sullivan cross-compound power-driven air-compressor. These high-duty air-compressors may be driven by belt pulley, by an electric motor mounted on the crank shaft, or by an impulse water wheel. They are built to displace capacities ranging from 1200 to 3000 cu. ft. of free air per minute, in a variety of cylinder size combinations for terminal pressures from 60 to 150 lb. per square inch.

Mark Manufacturing Co., Chicago, Illinois. 'The Mark Cold-Drawn Steel Union' is the title of a new publication of this Company. This union is composed of the three usual parts, the bottom, the thread end, and the coupling nut. All of the parts of the Mark union are made by the same process, that is, drawn and pressed from cold flat steel, by a series of operations performed in powerful presses. The publication is fully illustrated, showing the process of manufacture of these unions.

The Traylor Engineering & Manufacturing Co., Allentown, Pennsylvania, has entered into a contract with the Knight-Christensen Metallurgical Co. for the exclusive manufacture and sale of the patented apparatus owned by the Company and used in the Knight-Christensen process. The Pennsylvania company is extensively engaged in the manufacture of smelting and milling apparatus and the taking over of the manufacture of the Knight-Christensen machinery by this Company adds another line to the Company's many products.

The Cleveland Rock Drill Co., Cleveland, Ohio, has for distribution Bulletin No. 33, which is devoted to a discussion of Cleveland hand rotated hammer drills. These drills are made in three sizes and adapted to mining, quarrying, and construction work. The material used in their manufacture is selected with special reference to the service required. The forgings are made in the shops of the Company and are heat treated as soon as made and again after being partly machined. Each of the machines is designed to give the best service when operated at an air pressure of 80 lb. at the drill. The Company maintains an engineering service which is available to the users of drills.

The Bucyrus Co., Milwaukee, has in operation two dredges, the *Gamboa* and *Paraiso* at Culebra cut, Panama, which are described in *The Excavating Engineer* for November. These dredges are the most powerful in the world. The pontoons were towed to Colon and the gear assembled there. Each boat has a displacement of 1500 tons. The boom with its machinery weighed 66.5 tons and the dipper handle 40.5 tons. Since the dredges started work they have been digging an outcrop dike of trap rock, and during the 30-day test the *Paraiso* lifted several 10 to 30-ton boulders each day, and one of 50 tons weight. The capacity of the dredges is now up to 125,000 cu. yd. per month, the work being of the severest character.

Allis-Chalmers Manufacturing Co., Milwaukee, Wisconsin, has just issued Bulletin No. 1088, which is devoted to distributing transformers. In these transformers there are three cooling surfaces, instead of one as is the common practice, together with a continuous natural circulation of the oil. The transformers are of the so-called core type, having a single magnetic circuit with the coils wound on the two longer legs of the rectangular shaped core. The Company also has for distribution a new bulletin, No. 1089, which is devoted to reversing motor planer drives. The motor and control equipment are designed as one operating unit and the apparatus has been designed to give the best service both mechanically and electrically for the precise character of the work to be performed.

Pelton Water Wheel Co., San Francisco, California, tiennes para distribucion un boletin 'La Rueda Hidráulica Pelton' de las que hay millares en uso en todos partes del mundo, proporciona la fuerza motriz mas barata y segura. Su formacion es muy sencilla y sus partes de trabajo consisten de una rueda á cuyo borde se han unido tazas ó cubos de patente. Un chorro de agua saliendo de un boquerel y dando en el centro de los cubos produce el movimiento de rotacion el que á su vez es trasmitido por medio de correas y poleas á la maquinaria que se desea mover. Las Plantas de fuerza motriz hidráulica consisten generalmente de tres partes separadas: (1) la acequia ó canal para llevar el agua desde la fuente de abastecimiento á la toma; (2) la tubería de acero que lleva el agua cuesta abajo desde la toma á la rueda hidráulica; (3) el edificio dónde se instala la rueda hidráulica y la maquinaria que se ha de mover con ella. En muchos casos no hace falta acequia ó canal, siendo la tuberia solamente la que lleva el agua desde la fuente de abastecimiento á la rueda. Tampoco es siempre necesario que el edificio dónde se tiene la rueda hidráulica contenga tambien la maquinaria que esta mueve. Cuando por cualquier razon se desee colocar la rueda hidráulica en un edificio separado del de la maquinaria que esta mueve, la fuerza motriz puede trasmitirse ya sea por medio de correaje, cable de alambre, ó Manila, ó bien por medio de trasmisión eléctrica. Los factores que deben considerarse para determinar el método mas apropiado para trasmitir la fuerza motriz son muchos y asi las personas que deseen comprar ruedas hidráulicas deben dirijirse pidiendo información á la Pelton Water Wheel Co. de San Francisco, California, ó Nueva York, E. U.

MERIT rating is being applied slowly to workmen's compensation as well as to fire insurance. In whatever insurance plans the California mine operators adopt, the merit system will have large place. This is as it should be. The operator who protects his workings has a smaller risk and should have a lower rate.

PROMPT results have followed the conference of the Industrial Accident Commission and California mine operators. The Commission has submitted a proposal to furnish insurance, practically at cost, whenever the mine operators shall combine to furnish a business amounting to $100,000 per year in premiums. The amount now paid is several times that sum, so it would seem that such a combination is possible.

SUGGESTIONS as to possible oil and gas territory in northwestern Missouri and northeastern Kansas are made in a recent report of the United States and the Missouri Geological Surveys. While the prospects are not thought to be especially brilliant, the more favorable areas are noted. Many years ago Mr. J. E. Todd pointed out the presence of anticlines along the Missouri, and later Mr. W. H. Norton, of the Iowa Geological Survey, discussed the structure of the region. A deep well at Glenwood, Iowa, gave negative results, and one drilled at Nebraska City in 1906 was unfortunately located in the middle of a syncline. Other attempts were equally unsuccessful. The territory is worthy of a test, but needs more care and knowledge than has yet been developed.

GRADUATES of the College of Mines of the University of California have played a notable part in development and management of the world's great mines, and in many countries news of the death of S. B. Christy, dean of the college since 1879, will come with the shock of the loss of a personal friend. In these days of quick change it is rarely that a man stays so long in one position, but when he does the cumulative force of his years of work becomes overwhelming. Christy used this power which the years brought to him for the school and the profession rather than for himself. Indeed, his whole life was devoted to the school over which he so long presided. At another time we shall present a more detailed account of his career. Now we extend our sympathy, and express that of the mining profession, to his widow and children.

RIGHT-OF-WAY through New Keystone ground for a tunnel was refused the Inspiration Copper Company by the Supreme Court of Arizona, on the ground that the proposed use was private and not public.

A MODIFIED decree regarding smelter smoke has been issued, by stipulation, by the United States District Court at Salt Lake City. The most noticeable feature of the new decree is that definite provision is made for an inspecting committee with expert service. It is believed that the new decree will permit more activity at the lead plants and will also protect the farmers. The report of the Selby commission has been formulated and will be presented to the court next week. Judge Van Fleet, of the District Court at San Francisco has adjourned the hearing on the Shasta County fume cases until he can investigate conditions on the ground.

IN a recent address by Mr. M. W. Mix, president of the Dodge Manufacturing Company, on the subject of the development of trade with South America, Mr. Mix points out that there is a right and a wrong end at which to begin, and urges that buyers rather than sellers be sent out as the commercial missionaries into those countries south of us. Mr. Mix said in part: "Our business affairs have been considerably upset by the European war, but its effects have been far more severe upon South America. What would be our local situation today if every Chicago bank were owned by English, French, and especially German, capitalists, and if our industries were mainly based on such investments? That is largely the situation of Latin America. Her people wish to buy, but the markets in which they have been accustomed to sell are closed or greatly narrowed. The sources on which they have depended for fluid capital and for credit have failed for the time. Latin America's present need, therefore, is not for salesmen asking her to buy. It is for buyers of what she has to sell. If we find uses for her products—if we open a market for her goods to replace the market she had in Europe—then we establish credit on which she can buy our goods. The problem is not merely one of rushing salesmen and samples to people ready to buy and able to pay. It is one of organizing broader trade relations and reciprocal exchange of commodities. In the end, all trade is barter. It is exchange of surplus products. We are too apt to think of trade in terms of money only.

The sum of the matter is that if we buy from South America then she can buy from us. We must buy as well as sell, and in this particular case it is practically necessary for us to buy first, or extend credit, which is the same thing."

WORK FOR MINING LAW REVISION

On another page we present the report of the committee on mining law revision, as submitted by the chairman, Mr. E. B. Kirby, for consideration of the American Mining Congress at its meeting at Phoenix, next week. The report should be read and taken to heart by all interested in the development of mines on the public domain. It is apparent that another and a stronger effort must be made if revision is to be accomplished in any near future. Despite the widely recognized need of changing the laws to meet changed conditions, it has so far proved impossible to get Congress to provide even a commission to consider the matter and to make recommendations upon which Congress itself may act. There have been intimations, in which our own Washington correspondent has joined, that there is secret opposition from those who profit from the present jumble of misfit statutes and contradictory decisions that passes for a code of mining laws. If so, the opposition has been carefully concealed, since no one has, seemingly, been willing to come out in the open and maintain that no revision is needed. Dissatisfaction with the present laws is too widespread and too well founded to permit such a position to be maintained in public debate, and, while there are differences of opinion as to what changes should be made, and how revision should be accomplished, we have yet to find anyone who does not favor some change. What the mining men are now asking is merely that these widespread evidences of dissatisfaction be considered by a competent and friendly tribunal. Mr. Kirby has elsewhere summarized most excellently the demands of the mining men. These are:

1. That the revision be general.

2. That the membership of the commission be restricted to men whose qualifications for the work are known to the mining industry.

3. That the commission shall hold its public hearings within reach of the mining communities and give the public full opportunity to express its views.

4. That the commission shall have some reasonable time limit set upon its task.

This is all that is being asked. If the proponents of any particular modification of law can not make out a satisfactory case before a competent and informed commission, the change ought not to be made: it is certainly not unfair to ask that the men acting in this responsible position, one potent for so much to all phases of mining, should be men "whose qualifications for the work are known to the mining industry"; that the revision be general is necessary if it is to be satisfactory, since the whole structure of the law must be taken into account if a workable system is to be evolved—the proverbial blue patch on a red background is not more out of place than some amendments that have been made; and that the commission hear all sides and report within a reasonable period is in the interest of economy and efficiency. It is difficult to see how less could be asked if any good is to be accomplished. Details as to payment or non-payment of the commission are not of sufficient importance to warrant defeating the legislation. It is ridiculous that the United States government can not afford to study the rules under which it sells millions of dollars' worth of land, but there are patriots among mining men as in other ranks, and if the 'pork barrel' is really more important than the public interest, men can be found who will do the work without pay. Who, however, wants to take the responsibility of saying this is necessary?

Failure to pass on the bills providing for the proposed commission has so far been due, we believe, to lack of attention rather than to any real opposition to the measure. If there were no law against murder, some one would have to 'lobby' hard to get such a bill through any legislative body. It is not opposition that kills bills: it is lack of concentrated effort to make a particular bill stand out from the multitude. The mining men can force this through in a few weeks if each one will concentrate upon his own representatives at Washington and make clear that there is a real need for this legislation and an active demand for it.

We do not propose to re-state the grounds upon which revision is asked. The defects of the present laws, drawn with regard to conditions forty years ago and based upon wholly erroneous ideas as to the form and character of orebodies, are too well known to need repetition. The need is beyond argument. The practical point is what change is desirable and how to bring it about. To this we believe the correct answer is the proposed commission. This plan has already been adopted as most feasible, not only by the American Mining Congress, but by the Mining and Metallurgical Society. So far as such action is possible, the American Institute of Mining Engineers has also shown a disposition to favor the plan proposed. Unfortunately, the Institute also acts under laws adopted forty years ago and strenuous objections have been raised to its going upon record in any formal way. Mr. H. V. Winchell is serving as chairman of committees on mining law revision for both the Institute and the Society, and thanks to his active leadership, the Institute meeting of last February was notable for the interest expressed in this subject. While, for the present at least, he is estopped from any formal action on behalf of the Institute, the Society has both the machinery and the funds for an active campaign. With the co-operation of the Mining Congress, we believe that the matter can be so presented at Washington as to secure prompt passage of the necessary legislation. It is a large opportunity, and we hope the officers of the Society will rise to the occasion.

NATURAL GASEOUS FUEL

We have previously alluded to the peculiar fact that the production of certain mineral substances is generally looked upon as mining *par excellence*, while the production of others of equal or greater aggregate value is scarcely recognized as belonging to the mining industry, partly because the methods employed are not the traditional ones of the miner of digging shafts and excavating stopes, and partly for a variety of other reasons. Natural gas is one of the most important of these stepchildren of the mining industry, and it requires some mental adjustment to realize clearly that the annual production of this valuable fuel is worth about $90,000,000, or more than our lead and zinc output combined, considerably more than our silver output, and almost as much as the yearly production of gold. Every engineer knows that gaseous fuel can be utilized to better advantage than liquid fuel, and liquid fuel to better advantage than solid, yet the mining of coal is held in much higher regard than the production of either of the other two. This may be because coal mining is a very ancient art, while the production of gas and petroleum, except in China and parts of Asia Minor, is an industry with a history of little more than a half century. The petroleum industry, by reason of its importance and the vast addition it has made to the national wealth of this and other countries, has won a place for itself, but natural gas still is relegated to below the salt. For a long time, and still to a certain extent, gas was little more than a waste product accessory to the production of petroleum, and it was only gradually that local uses were developed for it. This brings us to the fundamental drawback of natural liquid and gaseous fuel; namely, their lack of transportability. Coal may be dug out in lumps, hauled about in any receptacle, and piled up in heaps until it is desired to use it. Liquid fuel can only be moved in carefully made tanks or pipelines, and if it is stored it is subject to loss by leakage and evaporation, besides being a continual fire risk. Gaseous fuel has all these drawbacks in an accentuated form, since it will escape through the tiniest hole, it can not be stored except at prohibitive cost, so that the user must be directly connected to the source of supply, and, furthermore, it is so tenuous that a pipe-line which will transport a large tonnage of petroleum will carry only a small weight of gas, and therefore the distances to which it can be economically transported are much less. The present high-water mark thus attained is the pipe-line, 120 miles long, which transports gas from the Midway field of California to the city of Los Angeles. It is reasonable to expect that the present tendency toward economy in use of fuel will lead to an accelerated rate of growth of its use.

The geographical development of natural gas is worth a passing note. Thirty years ago Pennsylvania was producing 4½ millions of dollars' worth, and a little was produced in New York and Ohio. Ten years later the Indiana fields had come in and were yielding more than Pennsylvania had a decade earlier, that state having meanwhile increased its yield somewhat, and the Ohio output having greatly increased. Kentucky, Tennessee, Kansas, Colorado, and California had all entered the arena with small yields. By 1904 West Virginia had developed so that it was the second state in value of output, Kansas had become one of the important states, and Oklahoma was just beginning. Last year the yield in West Virginia was valued at over $34,000,000, or more than one-third of the total for the United States: Oklahoma contributed $7,500,000 worth, while the value of the output of Kansas, which in the decade 1899-1909 had increased from $332,000 to $8,300,000, had declined to $3,288,000. California since 1910 has increased its yield from less than $500,000 to nearly $2,000,000. It must be remembered that these figures represent the value and not the quantity of the output, for the volume of natural gas which is yearly being wasted is almost unbelievable. Notable work in preventing waste has already been done by the Bureau of Mines, and during 1913 its representatives so supervised drilling in Oklahoma that two oil wells, which would have wasted 20,000,000 cubic feet of natural gas per day if drilled in the ordinary way, were prevented from causing any waste.

One of the most interesting features of the natural gas industry is the increasing use of gas for industrial purposes. The statistics prepared by Miss Belle Hill for the United States Geological Survey show that, although in 1913 there was a decrease in the use of natural gas for domestic purposes, there was a notable increase in the quantity used for industrial purposes, the price respectively of 27.33 and 9.4 cents per thousand feet having increased in both instances. Thus only one-third of the quantity of gas is used for domestic purposes, but it brings so much higher price that it corresponds to nearly two-thirds of the total value.

The importance of natural gaseous fuel in the zinc smelting industry is so well known as not to need reference. The production of gasoline from natural gas is a recent development, but already there are nearly 200 plants for its production, that in 1913 yielded 7,500,000 gallons of gasoline, valued at over $500,000. The light gasoline thus produced can be mixed with heavier distillates made in petroleum refining, so that the addition thus made to the national supply of this present-day necessity is even greater than the figures would indicate. West Virginia, Pennsylvania, Ohio, and Oklahoma are the principal producing states, and it is interesting to note that the average yield of 1000 cubic feet of gas is three gallons of gasoline. A less known use of natural gas is the production of carbon black, which is not a substitute for lampblack, but has its own uses, being better suited for making black ink, stove polish, and vulcanized rubber. The technology of the production of carbon black is still in process of development, and it is to be expected that an increased use of natural gas will be a characteristic of chemical engineering of the future.

As War Looks in London

By T. A. RICKARD

The Commission to aid the famishing Belgians is American in fact, although the inclusion of some Spanish officials makes it look international. The money so far is coming from Belgian, British, and American sources. Two shiploads of food have been delivered in Belgium, but it appears that the efforts of the Commission have been hampered and hindered by cross-currents of purpose. In the first place, the military problem cannot be ignored by the Allies. Now that the population is in dire distress and the German military administration is embarrassed thereby, comes the philanthropic proposal to furnish food from England and America. But Belgium is claimed to be a German province. Why should food be supplied from outside sources for the benefit not only of the poor Belgians but also of the Germans? It is true, the authorities at Berlin have guaranteed that the food sent by the Commission shall not suffer molestation from the military administration in Belgium, but any food sent to the country is, in effect, a gain to the German government now precariously established in that country. Another aspect of the problem is presented by the indemnities levied on various cities; for example, the $9,000,000 imposed upon a non-military and non-combatant city like Brussels. This levy in itself would pay for a good deal of food. These considerations cannot be overlooked, even if, as seems likely, they are put to one side just now in the desire to alleviate human suffering.

Two days ago I went to the Hotel Cecil to see the Sportsman's Battalion, which assembles at that famous hostelry. More particularly I went to see my friend J. H. Curle, the author of 'The Gold Mines of the World,' a writer well known on both sides of the Atlantic, and a former special contributor to the *Press*. The battalion consists of such men as himself, over age according to the recruiting requirements, but fit for military service and anxious to fight for their country. From 10 to 15 per cent of those now in the battalion are too old or otherwise unfit, but the rest are first-rate material. Curle tells me that they have come from every corner of the map. He himself had just returned from Guiana, another in his section hailed from Trinidad, another from the Argentine, a fourth from Singapore, and a fifth from the Gold Coast. Among those in this battalion, which is attached to the Royal Fusiliers, are several mining men: J. H. Curle, W. S. Holloway, F. P. Bray, A. G. Bevan, G. R. Nicolaus, and W. H. Rundall. They have now gone into camp at Romford, in Essex, to prepare for active service. Curle has a high opinion of his comrades; he says that he would go with them anywhere. They will give a good account of themselves, no doubt.

By the way, one of the London Scottish officers, writing home, explains that before going into action they had to spend several days getting used to the sight of the horrors of slaughter, which at first will nauseate and unnerve any man. The heaps of dead and dying, on both sides, on the battlefield in Flanders are such as to appall the average man. Another soldier tells me he had not believed the stories of mass attack until he was in the trenches facing one of these assaults. The Germans came onward bravely and so thickly that he felt sure that every shot he took must have gone through half a dozen of them. Then when our fellows used the bayonet they screamed like wounded hares. No wonder. "Did you ever cry?" I asked. "Yes," he said, "one day I had been firing fast when my rifle jammed. I blubbered. It was the worst thing that could happen. But I knew that the regimental armorer was in a cottage a couple of hundred yards to the rear, so I bolted across the shell-swept ground to reach him. Half way across I heard a roar and glanced over my shoulder to see that a shell had fallen in the trench just where I had been placed. A second later another shell smashed the roof of the armorer's cottage and killed him. I took cover behind the ruined wall and found a brick, with which I loosened the breech-block. Then I felt better."

London has been further darkened. The upper portions of street and railway station lamps have been blackened so that the light does not pass skyward. The use of powerful lamps on motor cars is forbidden. Orders have been given for the pulling down of the blinds in the railway carriages after dark, so that we go home in mysterious seclusion. When I go to the station, at six o'clock, the sky over the city is being swept by pencils of light from searchlight apparatus placed on various buildings. On others the air-craft guns are ready for the winged ships from across the sea. But we take it most calmly. A few bombs dropped on London would do more good than harm, from a military standpoint.

H. W. Turner, who has returned from Siberia, by way of Finland and Norway, says that the general prohibition against the selling of *vodka* has been accepted without serious protest and is working splendidly throughout Russia. He also informs me that the Russians are sending their prisoners of war to the Altai and other pleasant parts of Siberia. When I say 'pleasant,' I mean as beautiful and productive as the best parts of Colorado and New Mexico. The Altai is a fine country. Thousands of Austrians are now distributed along the Irtish, free to move about within a restricted territory, having given their parole. On the other hand, the German soldiers, who say that their military oath prohibits the giving of their word, are placed in concentration camps. The Austrians are finding employment and will correct the labor shortage, which, for example, is hindering work at the Riddersk and Zeranovsk mines. Undoubtedly some of these Austrians will remain in the country. War has often caused involuntary migrations that have enriched the country of exile. We shall keep a good many of the Belgians. You may get some of them in California.

November 5.

The American Mining Congress

The seventeenth annual session of the Congress will be held next week at Phoenix, Arizona. Below is printed the provisional program, followed by the report of the committee on the revision of the mining laws.

PROVISIONAL PROGRAM

MONDAY, DECEMBER 7, 1914

AFTERNOON SESSION

2:00 o'clock—Opening session, called to order by Joseph H. Kibbey, chairman of reception committee. Invocation. Address of welcome, R. E. Sloan, reception committee. Address of welcome, George W. P. Hunt, governor of Arizona. Address of welcome, George U. Young, mayor of Phoenix. Letter of greeting, Woodrow Wilson, president of the United States. Response by Carl Scholz, president. Five-minute responses by representatives from the several states. Selection of committee on resolutions.

EVENING SESSION

7:30 o'clock—President's annual address, Carl Scholz, of Chicago. Reception to the president and directors.

TUESDAY, DECEMBER 8, 1914

MORNING SESSION

9:30 o'clock—Report of the committee on taxation of metalliferous mines, D. L. Webb, chairman, Denver, Colorado. Address, H. A. E. Chandler, Phoenix, Arizona. Open discussion under five-minute rule of the general subject of mine taxation: (1) Should the taxes be so applied as to prevent the holding of mining claims, patented or unpatented, without substantial development work? (2) Should all unworked claims be assessed at a valuation equal to the price asked by the owner? (3) Should the state's power to tax be used to prevent the holding of mining claims for purely speculative purposes?

AFTERNOON SESSION

2:00 o'clock—Report of committee on mining investments, W. R. Allen, chairman, Butte, Montana. Address, 'Blue-Sky Laws,' John R. Burton, New York. Discussion under five-minute rule, led by E. G. Reinert, Denver, Colorado. Address, 'Why Optimism?' by George Otis Smith, director of the U. S. Geological Survey. 'The Needs of the Zinc Mining Industry,' Otto Ruhl, Joplin, Missouri. Address, 'Mining in New Mexico,' Fayette A. Jones, Socorro, New Mexico.

EVENING SESSION

7:30 o'clock—Annual meeting of members, followed by address by Joseph A. Holmes, director of U. S. Bureau of Mines.

WEDNESDAY, DECEMBER 9, 1914

MORNING SESSION

9:30 o'clock—Report of committee on prevention of mine accidents, W. R. Ingalls, chairman, New York City. Report of committee on general revision of mineral land laws, E. B. Kirby, chairman, St. Louis, Missouri. Address, H. V. Winchell, Minneapolis, Minnesota; David W. Brunton, Denver, Colorado. Address, 'The First Move,' W. G. Swart, Denver, Colorado. 'Legislation and the Mining Industry in Arizona,' Walter Douglas, Bisbee, Arizona. Paper, 'The Administration's Public Lands Policy,' John F. Shafroth, senator from Colorado. Paper, 'The Pending Federal Leasing Law,' T. J. Walsh, senator from Montana. Address, 'Conservation, State or National?' William P. Phillips, Austin, Texas. General discussion.

AFTERNOON SESSION

Visiting ladies will be entertained by auto drive and tea at the Country Club.

2:00 o'clock—Report of committee on electrical equipment in metal mines, H. S. Sands, chairman, Denver, Colorado. Report of committee on Alaskan legislation, Falcon Joslin, chairman, Fairbanks, Alaska. Paper, 'Federal Control of the Water Power of the West,' E. A. Wedgewood, Salt Lake City, Utah. Address, L. Bradford Prince, Sante Fe, New Mexico. Address, John Hays Hammond.

EVENING SESSION

8:00 o'clock—Smoker given by Phoenix Board of Trade.

THURSDAY, DECEMBER 10, 1914

MORNING SESSION

9:30 o'clock—Report of committee on workmen's compensation, Samuel A. Taylor, Pittsburgh, Pennsylvania. Report of committees. Paper, 'The Law and Compulsory Arbitration,' James A. Emery, Washington, D. C. Address, 'The Cost of Strikes,' Charles Piez, Chicago, Illinois. Address, 'Compulsory Arbitration,' Samuel O. Dunn, Chicago, Illinois; H. U. Mudge, Chicago, Illinois; Thomas L. Lewis, Columbus, Ohio; John A. Martin, Pueblo, Colorado.

AFTERNOON SESSION

2:00 o'clock—Report of committee on forestry relations, Robert S. Martin, Denver, Colorado. Address, 'Mining Rights on Indian Reservations.' Papers by M. A. Smith, Tucson, Arizona; Henry F. Ashhurst, Prescott, Arizona; Carl Hayden, Phoenix, Arizona. Address, 'The Mining Industry of Arizona,' Charles B. Clapp. General discussion under five-minute rule.

FRIDAY, DECEMBER 11, 1914

MORNING SESSION

9:30 o'clock—Final report of committee on resolutions. Unfinished business. Adjournment.

Automobile trips will be arranged for Friday afternoon and Saturday to various points of interest.

REPORT OF THE COMMITTEE ON REVISION OF THE MINERAL LAND LAWS

BY E. B. KIRBY, CHAIRMAN

Since the last annual convention, the American Mining Congress has taken every opportunity to press for the creation by the Congress of the United States of a commission which shall revise and codify the mineral land laws of the United States. Your committee takes pleasure in reporting that most encouraging progress toward the desired end has been made at Washington. A bill, No. 4373, providing for the appointment of the commission desired, was introduced in the Senate by Mr. Smoot and was approved by the Secretary of the Interior. The bill, after receiving some alterations, was favorably reported by the Committee on Mines and Mining, and was passed by the Senate on May 7. Meanwhile, on April 1, 1914, Mr. Taylor, of Colorado, introduced a similar measure (Bill 15288) in the House of Representatives which was likewise approved by the Secretary of the Interior and favorably reported back to the House by its Committee on Mines and Mining.

At that stage, Congress decided to restrict its legislative program for the remainder of the prolonged session to the trust bills and your representatives were in-

formed that no further progress with the revision bills would be possible until the next session. Later on, the administration measures relating to coal, oil, etc., were added to the legislative program, and it was understood that the revision bill would be included with these. This expectation was not fulfilled, and the House adjourned without action in the matter, so that nothing further can be done until the winter session.

Both the Senate and the House bills vary somewhat from the measure recommended by the American Mining Congress which provided for a commission of five members who should be selected by the President for their recognized knowledge and experience in the mining industry, as will be remembered. In the Senate bill, this was amended to create a commission of three members, two of whom should be lawyers and one a mining engineer. The House bill, on the other hand, permitted the commission to consist of five members, but provided that they should serve without compensation. While these alterations are unsatisfactory, it is believed that the best opportunity to make further efforts for their correction will be presented after the passage of the House bill and when it meets the Senate bill in conference.

Your committee believes that the most important qualification of the commission should be its ability to command the confidence of the mining communities, and that this end can be best attained by having at least five members and leaving the President free in making the selections. Moreover, the members should be properly paid so that the appointments may not be restricted to men of wealth and in order that the business may be undertaken in a serious way, befitting its importance. The House bill will shut out from any possibility of selection the vast majority of mining men, as it restricts the personnel of the commission to those who have the rare combination of a knowledge of the subject, a desire to work for it, and who, at the same time, possess such incomes and freedom from business duties that they can leave their own affairs for six months of arduous labor and bear the serious expenditures which cannot be included in government accounts.

At the proper time, further efforts will be made to have these difficulties considered by those who are in charge of the bills; but in any case, it is probable that a revision bill will be passed at the next session. In the meantime, public interest is growing and the forces massing back of the revision movement are steadily increasing. In the American Institute of Mining Engineers and the Mining and Metallurgical Society of America, no other matter of public policy has been commanding such interest as this. In both organizations, the sentiment in favor of a general revision is overwhelming, and each one has gone as far as it could in approving and aiding the movement. The American Institute of Mining Engineers has been specially restricted in its support by provisions in its constitution which bar it from taking up public questions, and an effort is now being made to have its sphere of activity enlarged.

In the meantime, the American Mining Congress remains as the only general organization of the great mining industry which is in a position to freely voice its wishes and act for its interests in any direction. There has certainly never been a time when these interests have needed co-operation and intelligent direction so much as they do now, and mining men cannot afford to have the activities of the Congress weakened through any lack of financial support. Practical experience has shown that to be effective, the recommendation of the congress upon any matter must be properly presented at Washington, and this requires steady persistent work by some one who can stay there. At present, there is no way of securing this until the secretary of the American Mining Congress is given the means with which to carry on his work in the proper way. This is absolutely necessary to supplement the efforts of your various committees, who can only act through correspondence and the occasional visits of their members. The mining industry cannot hope that any of the afflictions from which it is suffering will disappear by chance. The only help in sight is self-help—the labor and money contributed by mining men to the work of the American Mining Congress.

Appendix

Preliminary draft suggested for a joint resolution of the Senate and House

That Congress shall undertake a general revision of the laws relating to mineral-bearing lands and mineral rights within the United States and Alaska, and such revision shall cover mineral deposits of every kind except those of coal, oil, phosphates, and salines, which are set aside as the subjects of other and special legislation.

In view of the technical nature of the problems presented by the work, it is desired to secure first the results of the knowledge and experience which exist among those who are engaged in the mining industry.

To this end the President shall, within sixty days hereafter, appoint a commission of five members who shall be selected for their recognized knowledge and experience in the mining industry.

The commission shall consider the mining laws of this and other countries and shall hold public hearings in the principal mining centres of the Western states and Alaska, giving full opportunity for the expression of public opinion concerning the problems before it.

Its recommendations shall be presented in the form of a fully drafted mining code.

Within six months after the appointment of the commission, its report shall be delivered to the President, who shall within thirty days thereafter transmit it to Congress with his further recommendations, if there be any.

Members of the commission shall receive ———— per diem with expenses, and shall engage such clerical assistance as may be necessary for the work.

Clause providing for the necessary appropriation.

Lake Superior Copper Mining: Present and Future—I

By THOMAS T. READ

In 1872 the copper produced by the mines of the Keweenaw peninsula of Michigan represented over 95% of the total output of the United States. Year before last the output of the mines of that district only represented 15% of our total. The mines have penetrated to great depths, giving rise to many difficulties in working; the average copper content of the ore milled is now much lower than in former years; many mines are approaching the limit of their known ore reserves; and last year the operation of the mines was interrupted by a violent and protracted strike of the miners. It is not strange, therefore, that there is a growing public impression that the importance of the Lake Superior copper mining district, so concisely indicated in the name 'the copper country,' by which it is generally known, has already waned and that the region as a whole belongs to 'the eternal landscape of the past,' no longer deserving the amount of interest and attention it has so long enjoyed. It is my purpose to discuss, as briefly and lucidly as may be, what basis, if any, exists for such a belief, and to set forth what appear to me the most important factors on which any estimate of the probable production and life of these mines must be based.

It must at once be remarked that the decline in relative importance of the Lake Superior copper mining district is due to the rapid growth of the other districts and not to its own decline. Thus the production in 1872, which represented nearly the whole output of this country, was but 24,550,000 lb., while the production in 1912, which represented only 15%, was 216,609,000 lb. Up to 1910 (when the Western Federation of Miners began preparing for the strike of 1912 by cutting down the labor supply of the district), the yearly output of copper of the Lake mines had shown a steady growth, being in 1909, roughly ten times the production of 1872. Considered alone, therefore, the Lake Superior district has shown a steady growth over a long period of production, and the Quincy Mining Co., for example, has a longer record of continuous dividends than any other copper mine in the world, with the single exception of the Tharsis company, in Spain.

The mines of the Lake Superior district have been so often described that it is difficult for any writer to set forth much that is new. From the scientific standpoint the proper procedure would be to cite, in making points in the following discussion, all the previous articles dealing with them. Such a method of treatment is too often as tiresome to the reader as it is technically correct. The general reader is prepared to assume that a writer has made use of all the material available to his hand, following the precedent of Homer, as melodiously recited by Kipling, "whate'er 'e thought 'e might require, 'e went and took, the same as me." Those to whom a bibliography is a necessity will find an excellent one in 'The Keweenaw Series of Michigan,' by A. C. Lane, while a highly interesting account of the history of the district can be found in the most readable of all books upon it: 'The Copper Mines of Lake Superior,' by T. A. Rickard. It is my intention to use Mr. Rickard's book, published just ten years ago, for what military men would call a base of operations, as it is a well written, comprehensive, and accurate summary of conditions in

LAKE SUPERIOR COPPER REGION.

the district at the date of its publication. The changes which have taken place since then are highly significant and, avoiding repetition by presupposing a familiarity on the part of the reader with the book, I shall therefore attempt to discuss the present and probable future practice along the lines already indicated, including only so much of a general nature as is necessary to make my article intelligible when read by itself.

Geology

The copper deposits of the Keweenaw peninsula consist of native copper disseminated through vesicular flows of eruptive rock, chiefly of the diabase type, and interbedded sedimentaries, chiefly conglomerate. These deposits are remarkable for their size and persistence, but not as to their character, for the occurrence of small amounts of native copper associated with diabase flows and sills is not at all uncommon throughout the world. Elsewhere they are of low grade and of small extent, but in this region they have been worked along a length

AHMEEK 3 AND 4, ILLUSTRATING MODERN CONSTRUCTION AT THE LAKE SUPERIOR MINES.

of outcrop of nearly 100 miles, and at various horizons in a series of beds dipping 40°N.W. and exposed over a distance of, roughly, 5 miles at right angles to the strike. One of the beds has been productive for approximately 10,000 ft. on the dip. These are ore deposits on a truly magnificent scale, and the amount of attention they have attracted is quite justified by their significance. I have said above that the copper occurs disseminated through the beds. This is true as a general statement, but the copper also occurs in veins, as well as in masses of such size that they can scarcely be called disseminations. Curiously enough, the veins seem to be more important at the extremes of the district, both geographically and chronologically, for they are seen in their best development at the extreme northeast and southwest of the copper-bearing area (see map). They are worked in the former during the early days of the district, while the newest mine developed, the White Pine, a much faulted vein in sandstone, is so far to the southwest as to be beyond the edge of the map. The large masses of copper, one of which weighed as much as 130 tons, were the object of search during the early days; now they are less desirable, since they interfere somewhat with the routine of regular work, and also are less commonly found in the deeper levels. The most remarkable of the copper-bearing beds is a conglomerate, but this is not the rule, and the typical deposit of the region consists of native copper disseminated through the vesicular, usually the upper, portion of a lava flow, of the approximate composition of diabase.

The areal geology of the district, then, exhibits a series of flows and interbedded sedimentary deposits, dipping off to the northwest at an angle of from 30° to 70°, and with a general strike of N. 40°E., though it varies considerably from this in places, becoming almost east and west at the northern extremity of the area. These beds have an aggregate thickness at Portage lake of 22,680 ft., according to Lane, and are overlain to the west by the Freda sandstone. To the east they are cut off by the great Keweenaw fault, and abut against the Jacobsville sandstone. Within this large area workable deposits have been found at many points (as can at once be seen by a reference to the map), chiefly by the time-honored method of searching for outcrops, though in recent years the diamond drill is coming to be more and more employed for prospecting, as distinguished from development. This district has been glaciated, so that it is only in a portion of the area that the underlying rocks are exposed. In other places the glacial till extends to considerable depth, and these areas have not, in general, been so carefully prospected.

The Orebodies

In his interesting book, already cited, T. A. Rickard has related the story of the finding of one or more of the famous mines of this district. Practically all the older mines were found by detecting the outcrop of copper-bearing rock, or by trenching through the overburden in places where it was hoped to find the extension of lodes known to be productive elsewhere, for their persistence is remarkable. The Baltic, Isle Royale, Kearsarge, Osceola, Pewabic, and Allouez lodes can be traced for miles, showing workable amounts of copper in many places.

The copper is found either in conglomerate or in the amygdaloidal portion of lava flows. It is necessary to

put the conglomerate first because the most famous and richest lode of all is the Calumet & Hecla conglomerate. But the Calumet & Hecla is exceptional in many ways, and while there are other conglomerate lodes, the amygdaloids, as they are locally known, are the typical ore deposits of the district. These are of varying thickness, for the flows are not only of varying thickness as compared to each other, but they differ from point to point in the same flow, and, finally, the portion of the flow which is amygdaloidal, and consequently affords the pore spaces to receive the copper, is a variable part of the total thickness. The orebodies are therefore decidedly irregular in detail. A false impression of regularity may easily be derived as a result of the mining practice. A mine which yields large quantities of ore year after year, of a copper content, for example, of 25 lb. per ton, does not yield it from a lode averaging 25 lb. per ton; in fact no one may know what the average copper content of the lode actually is. The management having decided that 25 lb. per ton is the most profitable grade of ore to work, mining operations are so directed as to take out all the rich ore found and enough of the low grade to bring the average to 25 lb. The ore therefore often has no walls other than the arbitrary line of division between the ore which the mine captain considers good enough to mine and that which he considers too poor. This is scarcely true of the hanging wall, for the upper portion of a flow is apt to be more porous, and the ore is therefore likely to extend to the margin of the next overlying bed. Even this does not hold, however, for Charles D. Hohl has informed me that the top surface of the flows is characterized by irruptions of still liquid material through the partly solidified crust. The amygdaloidal structure transfers itself to the upper part of this irruption, and perhaps to the upper part of a second irruption; these outbursts being, of course, of limited extent. Thus, for example, the Osceola amygdaloid is, in the Calumet & Hecla ground, 35 to 40 ft. thick and about 15 ft. of the upper portion contains enough copper to average 15 to 16 lb. per ton.

Masses of copper of many pounds weight occur, and a single car may contain ore carrying 300 lb. per ton, while another might contain only 3 lb. per ton. I wish to emphasize this characteristic of regular irregularity, for it is the factor which above all determines and limits both mining and milling practice in the district. In order to see the district as it is today it is necessary to free the mind of its mental image of the Calumet & Hecla conglomerate, 15 ft. thick, all workable, carrying as much as 100 lb. copper per ton near the surface and 30 lb. per ton as worked in the deep levels today. The typical condition to be met in present and future mining is that described above. The important influence of this on mining methods is described later.

Another important characteristic which must be emphasized is the varying size of the copper particles. I have already referred to the mass of copper weighing 130 tons which was discovered. Masses of several hundred pounds weight are common, and the particles are of all sizes down to sheets of microscopic thickness and only 0.1 millimetre in diameter, occurring in the cleavage planes of the rock minerals. To make anything like complete recovery of the copper from the ore it is necessary to be prepared to handle pieces weighing a ton and also those weighing a hundredth of a milligram. This is indeed a difficult task to set a millman, and how

No. 6, THE NEWEST SHAFT OF THE MOHAWK MINING COMPANY.

remarkably well it is accomplished will be the subject of another chapter.

Persistence of the Orebodies

As a contrast to this characteristic irregularity of the orebodies their remarkable persistence must be equally emphasized. A half dozen lodes might be mentioned in which ore of workable copper content occurs for miles along the strike, while the Calumet & Hecla conglomerate has been worked to a distance of nearly 10,000 ft. below the outcrop on the dip and several lodes have been worked more than half as deep. These persistent irregular orebodies might perhaps be likened to the struggle for popular freedom in the world, which, while being marked by periods of lesser and greater activity, has nevertheless persisted through many centuries. However, as T. A. Rickard has said, even Methusaleh died. The boundaries of the workable portions of the orebodies have been determined in the upper workings, and it is only reasonable to expect that they will in every case, sooner or later, be encountered in depth. Thus, for example, the Allouez conglomerate was worked down to the twenty-first level in the Franklin, Jr., where it became too thin and too low in grade to yield any profit. The Calumet & Hecla conglomerate continues of good grade down to the thirty-first level of the Calumet & Hecla, or approximately to the boundary of the property, and is still workable in the depths beyond, where it has been exploited by the Tamarack. But it would appear that this remarkable orebody decreases in copper content with depth, for the ore taken out by the Calumet & Hecla in 1873 averaged 100 lb. copper per ton, the ore now being taken out by the same company averages 30 lb. per ton, and the ore mined in 1909 by the Tamarack averaged 19.6 lb. per ton. There is some danger of being misled by a comparison such as this, for the average of 100 lb. per ton in 1873 was undoubtedly maintained by leaving untouched blocks of ground that are now considered good ore, while the distinct rake of the oreshoot to the north may carry it over the boundary of the Tamarack ground. It must be understood that any comment on the Calumet & Hecla orebodies is largely a matter of inference, since the policy of that Company is not to permit visiting or resident geologists and engineers to go underground, while it is only within the past few months that C. D. Hohl has been appointed to act as geologist for the fifteen mining companies under the Calumet & Hecla control. The only present available evidence is the testimony of James MacNaughton before the congressional investigating committee in 1913, when he expressed the belief that the deposits decrease in copper content in depth.

It is equally hard to cite definite evidence from the other mines, for I have been unable to secure any records which would show whether a progressive decrease in depth can be noticed. It is easily seen from the records that the companies have from year to year produced ore of a steadily decreasing copper content, but, as already pointed out, this may be the direct result of lower working costs, thus making it profitable to extract ore that in preceding years would not yield a profit. This effect is cumulative, in that the ore produced this year not only contains many tons of material from the lower levels, that formerly would have been left standing, but also includes a considerable tonnage from the upper levels that was left standing in earlier years. Thus if the Company records show that a mine in 1900 produced ore averaging 20 lb. copper and now produces ore averaging 14 lb., it cannot justly be inferred that the upper workings averaged 20 lb. per ton and the lower workings 14 lb. per ton, for as a matter of fact the orebody might be just as good on the lower levels as in the upper workings. And with the failure of this means of determination practically the only means is lost, for in no case are the working faces in the mines sampled and no assay maps are available. It might be possible with great labor to compile from the mine maps and mill records, tables that would throw much light on this question of the persistence of the copper content of the lodes in depth, but no one has yet done so. It is indeed quite natural that the attitude of mind of the management of the various companies toward this question should resemble that of the colored pastor who was much annoyed by a leading parishioner who persisted in propounding questions dealing with the Darwinian theory, and like topics, in the weekly prayer meeting. Calling him aside one day he said, "Brudder Jackson, doan' do dat. Dem questions can all be answered, but de axin' of 'em in open meetin' will destroy all faith in 'ligion."

Development of Orebodies

No one familiar with the sampling of gold mines needs to be told that it is extremely difficult to determine by sampling the average metal content of orebodies such as those just described. Where a single piece of a few hundred pounds weight may contain as much copper as 25 tons of average material, the taking of a few samples would be merely misleading. And even if a ton sample were taken to represent the face of a drift, the cutting down and assaying of such a sample presents almost insuperable difficulties. The operators have met this difficulty very simply by not attempting to sample the orebodies. It must not be forgotten that what the miners first sought for were the masses of copper, easily distinguishable from their enclosing rock. There is much coarse copper in even the comparatively low-grade ore now worked. On a face which has been exposed two or three weeks even an amateur can at once distinguish the presence or absence of copper, for in the damp air the metal quickly acquires a surface film of oxide that reflects the light much like stove polish and can scarcely escape observation. In some way, too, the metal seems to multiply its visibility, and the back of a drift in ground that averages 50 lb. copper per ton appears to be literally full of copper. It is not difficult therefore for an experienced person to estimate the copper content of the ore in any exposed surface with fair accuracy, and it is very much easier and probably quite as accu-

rate to estimate that the ore will average 20 lb. per ton for the next six feet of advance as it is to determine with much effort that the exposed space averages 20.3 lb. and then be obliged to speculate whether it is likely to remain constant, increase, or decrease in copper content.

The Invisible Copper

Crude as it may seem to one who is in the habit of computing the average metal content of ore reserves by application of the method of least squares, the practice of directing not only exploratory work but also stoping, by the simple inspection of the ore seems therefore the only feasible way, under the circumstances. The method has obvious drawbacks. Along with the coarse copper there is always a certain amount of finely divided copper in particles too small to be detected by the naked eye, even were they not hidden within the cleavage planes of the minerals, just as the predatory insects of the night obscure themselves in the crevices of a bed. This was not important in earlier days, for this copper could not be saved by the then current milling methods, so no one cared whether 8 or 10 lb. per ton of invisible copper was present in the ore or absent. If the proposed leaching methods, discussed later, prove as successful as hoped, practically all the copper present in the ore can then be recovered and invisible copper will become quite another matter. One of the problems to be solved in the development of practice during the next few years will therefore be this difficult one of devising a method by which the total copper content of the ore can be easily ascertained.

The influence of old Cornish mining methods is still strong in the Lake Superior district, and in the earlier days they were the guiding ideal of practice. With ore deposits of a good stoping thickness, dipping at 45°, of such a character that their metal content could be easily estimated by inspection, and with Cornish miners to direct the work of exploration and development, it was inevitable that development should proceed by the ancient Cornish formula of sticking to the ore. Inclined shafts were sunk in the lode, drifts were turned off at hundred-foot intervals, pillars were left to guard the shaft, and as soon as stoping could be started it was at once begun. This is an excellent method of developing a small mine with minimum expense. If the mine is an unprofitable venture that fact can be ascertained before any great amount of capital has been spent, but if the mine proves a great success, the general plan of work thus laid out is a great handicap. In other words, the Calumet & Hecla, for example, is a huge mine which is laid out and operated like a small mine, and at no small disadvantage. This will be later discussed in connection with mining.

Because of the difficulty of ascertaining the average content of the ore of a lode, it sometimes happens that very large sums are expended on development work only to demonstrate that no operating profit can be made. The case of the Arcadian mine, on which nearly $2,000,000 was thus expended, has for many years been a classic example for professors of mining who wish to impress on their students the vital fact that it is highly desirable to be sure that ore is of workable grade before erecting a plant to treat it. In this case large lots of ore were treated in one of the neighboring mills. These large samples were supposed to represent the average of the mine, but it proved that the natural impulses of the miners had proved too strong, and instead of breaking the average material they had unconsciously selected that of better grade. In a more recent case one of the large companies spent $1,250,000 on the development and equipment of a property, only to demonstrate finally that it was an unprofitable venture. Diamond drilling costs $2 per foot, for the first 1000 ft., and increases 50c. per foot for each 500 ft. increase in depth thereafter. Hundreds of feet of drilling may be done without striking valuable orebodies, though a single hole may show a good core. It is commonly said that it takes a gold mine to make a coal mine, and these copper mines resemble coal mines in many respects, but with the drawback that although a coal seam, once found, can usually be depended on to persist over considerable areas, the copper of a promising lode may prove discouragingly patchy on further development.

Large Scale Operations Necessary

Of recent years trusts and monopolies have become bugaboos with which politicians and others scare their infants, the public, in order to incline them to their wishes. Nevertheless it has become abundantly evident to even the casual student of industrial progress that large aggregations of units have such valuable economic features that they have become an economic necessity, much in the same way that a dreadnaught, having demonstrated its value as an engine of war, has established itself as the standard vessel of every navy. The foregoing discussion has perhaps indicated that from now on the cost of discovering and developing new mines in this district is likely to be so great that only large companies can afford to take the risk necessary. It seems highly probable that many more workable deposits will be discovered by sufficiently courageous prospecting. The profits to be won are probably not nearly so great as in earlier days, while the expenditures and risks are certainly greater. The future of the district lies, therefore, in large scale development by a few large companies. This stage of its evolution is, indeed, already well advanced.

As already indicated, from now on the search for and exploration of orebodies must be conducted in a more ambitious and expensive manner than heretofore if much success is to be hoped for. All the easily discovered outcrops have been inspected, all the shallow overburden has been trenched. It now remains to search beneath the deep glacial drift, and to probe the beds in depth, in the hope that lodes which do not contain sufficient copper to be workable at the surface may prove richer in depth. A. C. Lane has frequently stated his belief that the ore deposits have no genetic relations with the

present topographic surface and that theoretically it is just as probable that a valuable ore-shoot will extend from 1000 ft. in depth down to 8000 ft., as that it will extend from the surface down to 7000 ft. in depth. Some recent evidence goes to support this belief. In the Franklin, Jr., the Allouez conglomerate was worked down to the twenty-first level, where it became so thin and low-grade that development work was stopped. Recently a cross-cut, driven on the thirty-second level, or more than 1000 ft. deeper on the dip, has cut the Allouez conglomerate at a point where it contains more copper than in the upper levels. Development work is now in progress to determine whether the ore so far uncovered is merely a rich spot in the lode or whether it is actually richer in depth than in the upper workings. Farther north, east of the Mohawk, the well directed and carefully studied diamond-drill work which has been done on the Mayflower and old Colony ground, under the direction of A. L. Dickerman, has disclosed deep-lying ore of good grade of which there is no indication on the surface. The drilling work has also disclosed the fact that faulting, to which little importance has so far been attached is in reality a significant feature of some at least of the orebodies. It is quite possible that if there had been careful and continuous geological study by trained observers, those ore-shoots which have already been worked out and abandoned in various parts of the district might now point to other ore-shoots in the same territory. This is, of course, only a possibility, but it indicates that it is highly desirable that exploration hereafter shall be done under the direction of trained geologists and not by rule of thumb. The difficulties are great enough in any event and should not be multiplied.

One feature of the new milling practice, later described, is that simple inspection of the ore taken out in development work no longer suffices to indicate whether it is workable or not. In some of the properties, notably the Winona, a considerable proportion of the copper is present in very fine particles. As already remarked, this copper was lost in the tailing in the old milling practice, and its presence was therefore a matter of no import. Now, by fine grinding and leaching, this metal can be recovered, and it is therefore necessary to know whether it is present or absent, as 3 or 4 lb. of invisible copper may often bridge the gap between operating loss and profit. The logical plan would be for one of the large groups to build a small test mill, capable of handling 25 to 50 tons per day, for its own use as well as for custom testing work. This method of sampling has already been adopted for the Ebner gold mine, in the Juneau district of Alaska, by the U. S. S. R. & M. Co., and the example might well be followed in the Lake Superior district.

COPPER OUTPUT of the Mt. Lyell mine, Tasmania, during the half-year ended September 30, was 3900 tons (8,736,000 lb.) from 171,000 tons of ore, 65,000 tons of which was from the North Mt. Lyell mine. Figures for the previous term are 3433 tons (7,689,920 lb.) from 163,500 tons of ore.

Comparative Drill Efficiencies

[We are indebted to William Hague for the following interesting comparisons between the work of several drills in the Champion mine. It will be noted that Mr. Hague finds that the character of the ground determines the first choice of a machine and that following that the character of the drill itself enters.—EDITOR.]

The Sullivan 'water piston' drill has been in use at the Champion mine, where the ground is comparatively soft. In one rise the following results were obtained, using first the Waugh 12-A: 44 drill shifts, 173 holes, 25 rounds, and 87 ft. advance. This is the equivalent of 2 ft. per drill shift; 3½ ft. per round; one man operating per drill shift.

Using the Sullivan water piston the results were: 81½ drill shifts, 468 holes, 78 rounds, 313 ft. advance, 2 men per drill shift. This is the equivalent of 3.84 ft. per drill shift, or 1.92 ft. per machine man; 4 ft. per round.

The reason this machine superseded the 12-A was that the water piston machine cleared itself more satisfactorily, giving a more rapid advance and at the same cost in labor.

In a drift, with soft ground, the following results were obtained with the Sullivan water piston: 6 drill shifts, 6 rounds, 49 holes, 21 ft. advance, 1 man per drill shift. In another drift the Sullivan ran: 116½ drill shifts, 65 rounds, 553 holes, 205 ft. advance, 1 man operating per drill shift.

It was found that with the Sullivan water piston in soft ground where the holes 'mud up' badly, the reciprocating motion is of great assistance in clearing the holes, as compared with a machine like the Leyner. In hard ground we have found the Leyner to be superior. We have no comparison between the Sullivan water piston and the Leyner at the North Star, because in the preliminary test the Sullivan water piston was unable to make a showing. As regards repairs on the Sullivan machine, two machines with a total of 810 drill shifts have cost nothing in repairs as yet, whereas the Leyner will average, at the Champion, about 25c. per drill shift.

THE Federated Engine-Drivers' and Firemen's Association of Australasia has caused a plaint to be served on 627 companies or individuals employing engine-drivers, firemen, motor attendants, boiler cleaners and others. A large number of these employers are in Western Australia, and are bound by industrial agreements which have a considerable time to run. A test will have to be made as to whether the Federal Arbitration Court has power to override the agreements and awards delivered and registered by the state courts.

NITRATE EXPORTS from Chile, South America, in August and September totaled 1,362,189 and 2,119,881 quintals (1 quintal = 101.61 lb.) respectively, against 4,313,476 and 4,118,906 quintals for those months of 1913.

Explosion Test at the Experimental Mine

By GEORGE S. RICE and L. M. JONES

One of the excursions arranged for the recent meeting of the American Institute of Mining Engineers at Pittsburgh, was a visit to the Bureau of Mines experimental mine, near Bruceton, Pennsylvania, which was made on the afternoon of October 9. Fortunately, it was a bright, clear day, and a large number of members of the Institute, accompanied by a delegation of the Pennsylvania State Inspectors, and other mining men, probably about 200 in all, went out to the mine by train and automobiles, and saw there a number of different kinds of demonstrations. They first entered the mine to inspect the arrangements for an explosion test and the 'barriers' that had been erected to limit the explosion, then saw, outside the mine, demonstrations with full size models of two of the rock-dust barriers, which had been set up in a way to show the cloud of rock dust discharged from them.

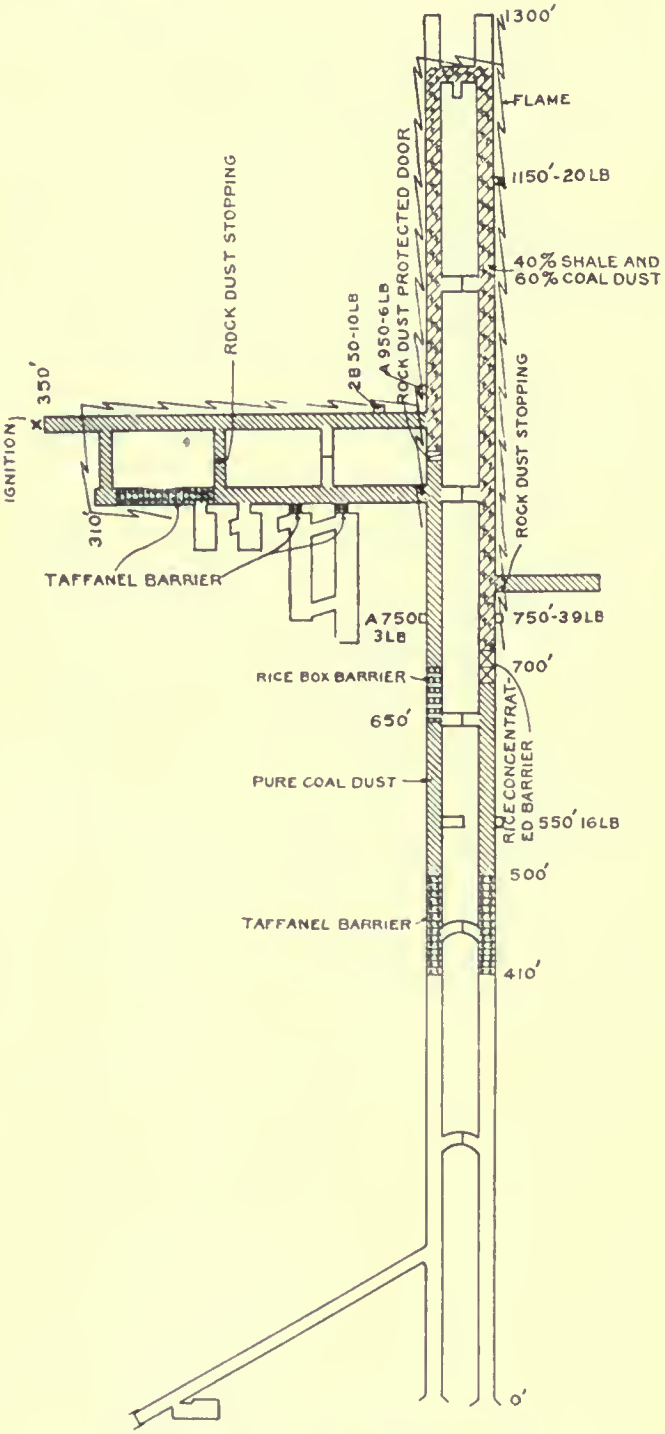
The Cement Gun in Mines

Afterward, there was an exhibit of the use of the 'cement gun' in covering with a layer of concrete some boards set up like a mine stoping. The concrete consisted of 2 parts of sand and 1 part cement, and wire mesh which was tacked on the boards served as reinforcement. This gun had recently been used in the mine to repair countless breaks in the concrete lining of the mine, caused during previous explosion tests; it had also been used to coat the inner part of the entries with a thin layer of 2 parts sand and 1 of cement without any reinforcement. The object of the coating was two-fold: to enable the entry to be more easily cleaned after each test, and to see whether the coating would protect the shale and bone coal roof from air-slacking. The conditions are somewhat severe at this mine on account of the explosion experiments, so it is hardly a fair test of the durability of the coating. It is hoped that this method of protecting the roof and walls may be durable in commercial mines, and if so, it would be a great economy to employ it, and indirectly it would add to safety in the prevention of falls.

The Explosion Test

After these exhibits the visitors moved up on the hill over the main entries to witness the explosion test. After the word had been given that the electrical connections had been made into the mine, and the physicist had made his tests to determine that the electric circuits were complete, warning whistles were blown, and 30 seconds later the explosion was started by throwing an electric switch in the observatory.

The first evidence issuing from the mine was a puff of light dust, accompanied by a muffled sound coming from the mouth of the air course, followed by a stronger and more continued puff of dust and smoke from that entrance; while this was issuing there was a puff of light dust from the main entry, and after an interval of several seconds this was followed by a prolonged outburst of dust and smoke accompanied by a crashing or booming sound. The explanation of these separate puffs and sounds appears to be that the first small puff coming from the air course was the shock wave from the cannon; the second and larger one was when the pressure wave



EXPERIMENTAL MINE ARRANGED FOR TEST.

issued from the explosion in the butt entry; the first puff from the main entry appeared to be caused either by the shock wave from the cannon, or the shock wave from the explosion itself in the butt entries; the larger burst of dust and smoke was due to the explosion in the main entry, which as the manometer records later showed, attained its maximum immediately before striking the concentrated barrier.

Perhaps one of the most striking features of this experiment was the demonstration of the present knowledge of dust explosive phenomena which enabled those in charge to plan the conducting and limiting of an explosion along a predetermined path.

Owing to the explosion being well in the interior of the mine, and as the fan was set barely to turn around, no smoke or dust was observed from either entrance after the outbursts above mentioned. A demonstration was then given by two mine-rescue crews of five men each from the Bureau, of the oxygen breathing apparatus; the advance party entering the main entry carried a guide rope, also a canary to observe whether or not it would be affected by the fumes. Owing to the retraction of the gases after the explosion the party had to go in 600 or 700 ft. before encountering the afterdamp, which affected the canary. On the coming out of the squad, the fan was started, to blow out a large amount of smoke and gas from the main entrance. Then ventilation was reversed and many of the visitors, including inspectors, entered and observed the effects of the explosion, getting a good view.

In conclusion, it might be stated that all of the explosion-checking devices used in this explosion test have been tried many times in the experimental mine explosions, and all of them with the exception of the Taffanel barrier, which has failed in low-pressure slow moving explosions, have always proved effective in stopping explosions. Installation of any of these types for separating different splits, panels, or sections of a mine from each other, or the other parts of the mine would undoubtedly be a big step in advance toward reducing the number of lives lost in large explosions. The Bureau engineers are now preparing a publication describing these devices, and it is strongly recommended that they be installed in bituminous mines in connection with a definite program of making coal dust inert by watering or rock-dusting.

Hoisting Accidents in Western Australia

The annual report of the Department of Mines of this state contains a mass of interesting information, and among the hoisting accidents the following occurred:

At the Golden Horse-Shoe, Kalgoorlie, there were three mishaps as follows: (1) An engine-driver had just emptied a skip of ore, when his attention was diverted to reply to a question from the chief engineer, and on receiving a signal from below to hoist, he turned on steam without noticing that he had not reversed the engine. On seeing his omission he applied both brakes, but too late to prevent an accident. The skip struck the safety thimble and hung up on the safety hooks and side grippers, releasing the rope. The Whitmore overwinding device was out of action at the time. No damage was done. (2) A case of overwinding occurred, in which the hoisting engineer, who was hauling ore at the time of the overwind, had the cage at the top landing, and on applying steam to lift the cage off the chairs the reversing lever became fast, and before he could pull it back the cage was at the ring, which sheared the copper rivet in the safety hook and released the rope. No damage was done to the cage or rope. (3) The next accident was also a case of overwinding, through the driver, while in the act of applying the foot-brake, missing the step and lurching forward, with the result that his left hand carried the steam handle forward and applied more steam. This gave the engine an impetus which carried the cage into the safety thimble before it could be stopped. No damage was done to the cage or shaft.

At the Eclipse mine, the engine-driver fainted while lowering two men to No. 5 level, and allowed the cage to run down to the shaft bottom, causing slight injuries to one of the men. On coming to his senses the driver found one cage hung up in the safety hook, and the other at the bottom of the shaft with nearly all the spare rope off the drum. Later on in the year the same driver was killed by his engine running out of control under circumstances which point to his having most probably fainted again.

The two following took place at the Great Boulder mine: (1) An overwind occurred through the driver losing control of his engine, because of the starting valve opening more easily than he expected. He was new to this work and had no right to drive the engine, as his certificate was restricted to geared engines and locomotives. No damage was done. [All hoisting engineers must pass an examination of general competency before being allowed to take charge of an engine.—Editor.] (2) Another overwind was caused by the driver allowing his attention to wander while hauling an empty cage. The copper pin in the safety hook was sheared, and the cage hung up in the thimble. An inquiry was held by the board of examiners, resulting in the driver being restricted from driving first motion hoisting engines for twelve months.

While hauling water at the Great Fingall, at Day Dawn, the engineer states that the tank hung a little when near the kick-up while being raised, and on his applying a little more steam suddenly went up to the wheel. He immediately shut off steam and applied the brake, but not in time to prevent the overwind.

Gold exported from Colombia, Central America, in August and September amounted to $546,000, compared with $471,000 in that period of 1913.

The Platinum Deposits of Germany's Paleozoic

By P. KRUSCH, Translated by F. SOMMER SCHMIDT

*If the known locations of platinum deposits are put on the geologic map of Dechens they appear scattered around Freudenberg, Siegen, Meschede in Siegerland, Sauerland, and Westerwald. Geologically the lower and middle Devonian as shown by Dechens are questionable. The platinum even in these formations is not confined to any one horizon, but varies considerably. On this map the geology of the districts under discussion appears very simple. Large areas have the same color. The science of that day did not give proper stress to the geologic structure. Neither folds nor faults seemed to be considered. During the past year the Royal Geologic Society of Berlin has begun a special geological survey of the district. This specialized map brings out the fact that the oldest platinum-bearing formation known to date, belongs to the 'Gedinnien' and may therefore have to be reckoned as Silurian. Following this we note a series of most varied horizons irregularly distributed up to the uppermost middle Devonian where the shales are still subject to mineralization. The distribution of platinum is closely dependent on the stratigraphy and structure of the district.

In such districts as I have examined, the slates and graywacke formations play the main part. Platinum has been found in diabase and basalt, but as I have not determined this, I will restrict myself to the former formations. In isolated instances the slates have carried more platinum than the graywacke. The Siegerland miner lays great stress on the cropping of graywacke.

Microscopic Studies

I have made a microscopic study of the platinum-bearing graywacke formations. The normal graywacke is an elastic rock which consists mainly of quartz and slate which is bound with a clay cement. It is therefore made up of the fragments of other rocks. The fragments were laid in water with imperfect separation by specific gravity. Frequently the graywacke contains feldspars which are partly kaolinized. Denckmann found such conglomerate with distinct granite pebbles. It is reasonable to assume that the feldspathic matter of these rocks came from this granite. There is at present no granite at the surface in this district, nor in the underground workings. It is safe to say that under these known formations there exists a granite which may be considered the basal formation. The old Paleozoic sea disturbed parts of this basal granite and transported pebbles of this granite to make the newer formations.

The microscopic study reveals that the cement of the rocks is not merely clayey or silicious, but is also carbonaceous. The younger formations, bearing platinum, gold, or zinc are distinguished by the cement regardless of geologic age. While the majority of the younger sediments are of loose texture, the graywacke are really cemented.

The platinum-bearing beds belong to the marine sediments. That the surf is capable of concentrating particles of gold has been shown at Cape Nome, Alaska, where the gold nuggets having been transported by the sea show etchings which cannot be seen on the fluviatile gold not far distant. As a result of microscopic investigation, it is safe to say that the ore minerals are partly concentrated in the cement and are more rarely found in the fragments which have been recemented to form the graywacke.

Accessory Gold

Of great interest are the occasional gold particles found in the slides. They are extremely small and are found in the cement. This appearance of gold was not surprising to me. With high magnification, 240 to 1, small black scales can be seen in the cement, very seldom in the quartz. It is impossible to tell anything about them under the strongest power. They are easily distinguished from the coarser graphite scales which are seen occasionally. They frequently show crystalline structure. By very fine grinding it is often possible to float these specks on water. Up to now I have not gathered enough of them to make a platinum determination. Among the material that floated was graphite, sericite, mica, and gold. As I did not find any other platinum-bearing ore in the graywacke, I am forced to assume that the precious metals are associated with these specks, particularly as they are found especially in the cement. What is more striking is that these specks are sometimes found in the quartz.

Due to the fine dissemination of the black specks, one naturally thinks of the transportation by ground-water, which circulates through the capillaries of the graywacke and should loosen the cement to some extent. The released platinum specks would then mechanically find their way to fissures. The mechanical transportation theory cannot be substantiated by the light of present knowledge. The theory contradicts our experience with the chemical and mechanical ineffectiveness of ground-water in underground circulation.

Of particular value to the investigation of the origin of the graywacke fragments is the segregation of certain constituents. Pufahl has treated 200 grams of finely ground pulp for weeks with hydrofluoric acid and concentrated sulphuric acid. After the first attempt, there was still quartz in the residue, while after a second trial the residue was free from quartz. The insoluble consisted of 0.044 gm. of heavy precious metal resi-

*Abstract of an address made before the German Metallurgical and Mining Society and printed in *Metall und Erz.*

due and disintegrated chrome iron ore. With this precious metal residue there was considerable zircon with its characteristic radioactive rays. In one residue a small amount of platinum was determined which figured on one ton of residue would amount to 1.15 gm. The extraction was made in a platinum crucible and it is not impossible that it may have been derived from that source.

Chemical Combination of the Platinum

Pufahl determined the presence of the following metals in the ore: Cr, Pt, Ir, Fe, Au. Hommel determined Cr, Ni, As, Sb, Fe, Cu, Pb, Zn, Ag, Au. In this aggregate it is well to separate the earlier ones from those that came later. The later ones would be Cu, Pb, Zn, As, Sb, Ag. The original ones are probably Cr, Ni, Fe, Pt, Ir, Ag, Au. The later minerals are probably derived from basic eruptives. Until now it has been impossible to get any idea as to the origin of the platinum or its chemical combinations.

Primarily we recognize the presence of the precious metals in the peridotites, namely, olivine-bearing rocks. This was determined in the Urals at different points. In fact there were locally some rich deposits in these rocks. In this case the precious metals resulted from magmatic segregation. The chemical combination in this case was determined as Cr, Ni, Fe, Pt. Comparing this with the work of Pufahl and Hommel shows a marked agreement.

In recent years a basic eruptive has been found in Canada which contained Cr 8.46% and 1.2 gm. of platinum per ton. It is of further interest that Johnson of Ottawa and Miller of Toronto could determine microscopically thousands of minute diamonds in a single slide, while others were free of diamonds. It is the presence of these diamonds that distinguishes the Canadian rocks from those of the Urals, but the combination of Cr and Pt will be noted as common to both. In Canada some platinum is obtained from nickeliferous pyrrhotite, which being a vein product in an eruptive formation gives us an eruptive origin for the platinum. The observation that precious metals seldom find their way to orebodies that have been built through the agency of water is important in a negative way for this discussion of the origin of natural platinum concentration. This observation is in line with laboratory experience which shows that platinum goes into solution with much difficulty as compared with gold.

The principal production of platinum is in the Urals and a little from British Columbia, in which regions the deposits result from the destruction or disturbance of primary deposits reformed through the agency of water. While the mineral is not in commercial quantity in the primary deposit, the distribution of the mineral in the secondary deposits has permitted commercial extraction. A comparison of these well known deposits with the newly discovered ones in the Rhine slates shows that the platinum in these latter show the same chemical association as the primary deposits in the Urals and British Columbia. One is practically forced to the conclusion that in the Rhine slates the origin is connected with a basic eruptive, probably peridotite. To differentiate the platinum-bearing graywacke from the Ural and Canada formations, it can be said that they have a great geologic age and were consolidated by a cement.

The granite pebbles in the conglomerate point to the existence of the granite in depth. They belong to the basal foundation which is overlain by the graywacke to an unknown extent. This basal complex could also contain the platinum-bearing basic eruptives and the primary gold. The sea during Silurian and Devonian times disturbed this basal complex and transported the precious metals into certain definite strata. Later these platinum-bearing beds were again partly disintegrated and the fragments cemented in younger, higher horizons. This explains the wide distribution of the precious metals through so many horizons. They are the product of continual destruction of older beds and the building of new sediments.

The search for the primary deposits, namely, the basic eruptives, is not promising, data as to the depth of the basal complex are lacking, and experience in the Urals and Canada with this type of deposit is not encouraging. The distribution of local rich bodies was too irregular to make it an attractive economic project.

The Platinum Content of the Graywacke

As this is a matter of precious metals, I will depend only on my own sampling and tests. I used the greatest care, taking 2-kg. samples which were lead-sealed in boxes on the spot. In addition to these I took larger samples weighing from 20 to 40 kg. and put in the usual sacks. As I could not give these sacks the attention I desired, I only lay stress on them in so far as they agree with the sealed samples. In testing this material, it is necessary to use a fine mesh, namely, 280 to the inch. From my experience it is desirable to use the largest possible quantity of pulp. In the dry work, never less than 200 gm. and preferably 300 gm. should be fused. In the wet methods, 1 kg. should be used. If platinum tests are made in different laboratories, or if the same test for platinum is made in the same laboratory several times, surprisingly divergent results will be obtained. For example:

First test:		
Laboratory	A	30 gm. per ton
"	B	trace
Second test:		
Laboratory	C	33.5 gm. per ton
"	D	3.8 gm. per ton
Third test:		
Laboratory	E	8.0 gm. per ton
"	F	0.8 gm. per ton

To determine the cause of these great discrepancies requires most painstaking investigation. It used to be believed that the platinum of the graywacke behaved abnormally while the precious metals were in the gel form in the rocks. The first one to advance this theory

was Schreiber, the discoverer of platinum in the Siegerland. He has doubtless some justification for this assumption, because, first, the gels have the property of appearing in finest division in the rocks, and second, colloidal platinum solutions are known. The question whether a precious metal occurs as a gel cannot be answered by a chemist, but rather by a petrographer, because the gel is easily distinguished optically from crystalline bodies, and this cannot be done chemically. Schreiber was really in error when he assumed that the difficulty in platinum chemistry had something to do with the gel form. If platinum is in the gel form, this can work no hardship on the chemist with the dry method, because gel is converted into the crystalline form by great heat. As it is possible to distinguish minute crystal fragments in the black specks, it is probable that in this case it is not a question of gels, but of crystalline structure.

There must therefore be some other reason for this discrepancy in results. It is either an error in analytical method or the original distribution of platinum in the rock. I am loath to admit any possibility of error in the chemical work. I am inclined to agree with Pufahl that the irregular distribution of the metal, in spite of the great fineness and the most careful mixing, is accountable for incorrect averages. We are already acquainted with similar cases.

If platinum is alloyed with iron in the graywacke, then it is not crushed equally with the quartz in the ball-mill. This difference would be also caused by the difference in brittleness of the two minerals. Under these circumstances a flour would result in which platinum specks are irregularly distributed. In taking the sample it would simply be a question of whether a few grains had been caught to give a high assay or whether none had been drawn to get a blank. If irregular distribution is responsible, then assay results cannot be figured on the ton, but apply only to the individual sample.

It is then impossible to establish the average in this way. The practical inference from all this is that we can only depend upon actual production which is capable of being demonstrated on a small scale for experimental purposes. Only the most exacting tests on samples of one ton and the extraction of the contained platinum can guard us against error.

Methods of driving mining machinery are varied, and in Western Australia, out of a total of 3422 plants, electric motors led with 1333; steam, 1309; compressed air, 27; oil engines, 541; and suction gas engines, 163. In the last named class, the down-draft type of producer using wood was installed at five government mills, costing 10.32 and 10.86 cents per hour run at two plants, against 16.4 and 19.8 cents at two others using charcoal, the mills containing 5 stamps each and other apparatus. The 10-stamp mill gas-engines, using charcoal, cost from 32.8 to 23.2 cents per hour run. The consumption of fuel was 1.05 to 1.45 lb. per brake horsepower.

Labor Union Proposals in Western Australia

*The annual conference of the Westralian Goldfields Federated Miners' Association was opened at Boulder City on November 23. Delegates from all parts of the eastern goldfields attended, and many important matters were discussed. The following were among matters proposed:

General Executive Committee—1. Consideration of affiliating with the Miners' Federation of Australia. 2. That rule 21 be amended.

Kalgoorlie and Boulder Federated Miners' Union—1. That contract and bonus system be abolished. 2. That night shift in mines be abolished. 3. That 44 hours constitute a week's work underground, inclusive of crib (lunch) time. 4. That the maximum height of stopes be not more than 12 ft. 5. That the practice of men shoveling under stopes be abolished. 6. That the practice of lowering and hauling men in cages hung under skips be abolished. 7. That the practice of rigging Holman hoists directly over winzes be abolished. 8. That the 1913 Mines' Regulation Act Amending Bill, with amendments, be again submitted to parliament. 9. That boards be constituted to examine foreigners as to their ability to speak the English language, with power to grant certificates to those considered proficient; the employment of any non-certificated foreigner to be an indictable offence on the part of the manager responsible. 10. That the state appoint public *accouchcurs*. 11. The question of continuing to pay *Westralian Worker* (the union weekly paper) dues from the funds of the association be considered. 12. That capitation dues be reduced. 13. That general rule 18 be struck out. 14. That fatal accident allowance be discontinued in cases where the dependents benefit under the Workers' Compensation Act. 15. That uniform rate of accident pay be recommended. 16. That subclause (e) of general rule 36 be deleted and insert the following: "All ballots taken shall be on the compulsory preferential system." 17. Amendment of the Workers' Compensation Act. 18. That overtime be paid for at the rate of time and a quarter, and double time for Sunday work. 19. That pay-day be fortnightly (every two weeks). 20. That the workers' representative on Court of Arbitration be elected by congress. 21. That the Trade Union Act be amended on the lines as laid down by congress. 22. That the office of general secretary be reconstructed. 23. Uniform rules and badges. 24. That the matter of granting clearances to unaffiliated unions be considered. 25. That the placing of candidates' names on ballot papers be considered. 26. That the Arbitration Act be amended. 27. That conference consider the size of trucks used in the mines. 28. That conference define a winze, shaft, and general mining terms. 29. Every mine shall be under a manager, who shall be responsi-

*Abstract from *The Kalgoorlie Miner*.

ble for the control, management, and direction of the mine. The manager shall be registered as the holder of a certificate of competency; he shall have had at least five years' practical experience. Second-class certificates shall be given to under-managers on the same conditions. Examination for certificates to be obtained from a board to be appointed for the purpose. 30. The Mines' Regulation Act be amended to provide for the appointment of check inspectors, and that the miners' union shall have the right to appoint an expert for the purpose of investigating any case in dispute regarding matters covered by the Mines' Regulation Act. 31. Each inspector of mines shall make a quarterly report on the condition of the mines in his district. A copy of such report shall be forwarded to the secretary of the miners' union. 32. That all inquiries into mining accidents shall be by a board, the members of such board to have practical experience in mining, and to represent workers and employers; it to be presided over by a district court judge, or a person accustomed to the technicalities of taking evidence. 33. That the inquiry into any mining accident where life is lost commence within one calendar month of the date of such accident. 34. That the workers' representative on the proposed board of inquiry be elected annually by members of the union. 35. That the Mines' Regulation Act be amended and provide protection to workers called on to give evidence on any matter relative to dangerous and defective mining conditions, against victimization by employers. 36. That all employees working in or about a mine be supplied with a copy of the general rules (free of cost) of the Mines' Regulation Act.

Gwalia Union.—1. That the capitation dues of 25% of contributions to the executive be reduced. 2. That the 30% of the capitation dues paid to the *Westralian Worker* by the executive be discontinued. 3. That the conference is in favor of procuring badges for all members of the federation, and that conference decide on style of same, and the executive be given power to provide the necessary cost. 4. That this federation refuse to grant any financial assistance to any labor body in the state that may be engaged in any industrial dispute, if action has been taken without first getting the consent from the district council with whom it is affiliated. 5. That a committee be appointed by conference to suggest amendments to the present Workers' Compensation Act, the same to be dealt with by conference and sent on to the parliamentary labor party, with a request that a new bill be introduced at the earliest opportunity.

Norseman Union—1. That parliament be asked to define a shaft or winze, as used in connection with mining operations. 2. The definition of the term 'rise' as used in mining operations.

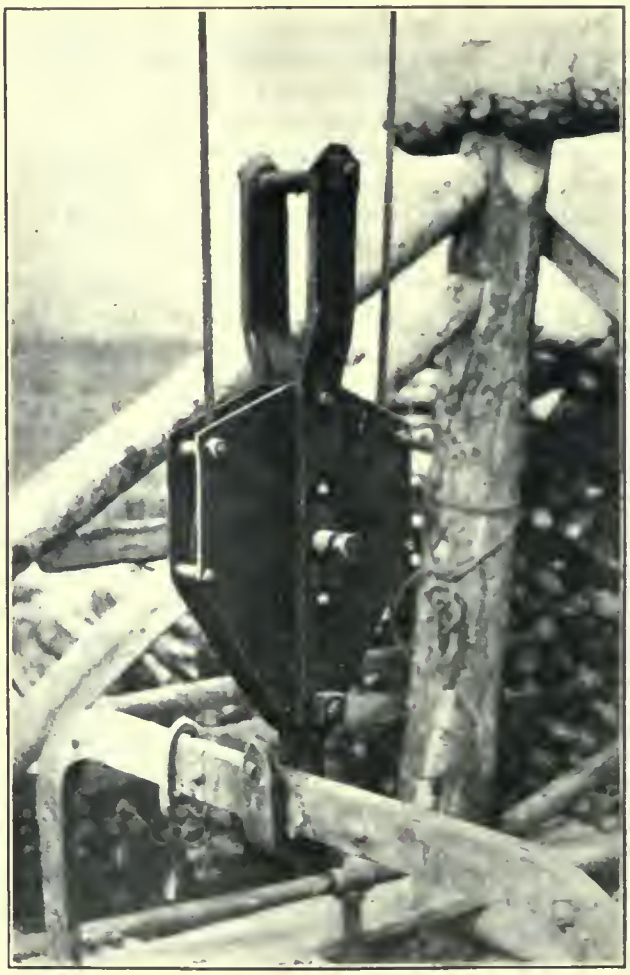
Coolgardie Union—1. The nationalization of the medical profession. 2. That the government be urged to provide legal advice free when plaintiff or defendant makes application for same. 3. That our laws be printed in English. 4. The abolition of state governors. 5. The reduction of representatives in both state houses of parliament by 50 per cent.

Marvel Loch Union—1. That a ballot be taken of the whole of the members of the W. G. F. M. U. with a view to the abolition of the contract system. 2. The government be requested to insert a clause in the mines' bill providing for the abolition of rising ground, excepting when absolutely necessary, and that the hours of labor in it should not be more than four-hour shifts. 3. We recommend to the government that more consideration should be extended to prospectors by way of reduction of rents, etc. 4. The total abolition of the use of telescope machines.

Menzies Union—1. That conference adopt a uniform design for the presentation medal to stewards and other union officers.

A Well Guarded Sheave

Where ropes and tackle are in use there is considerable danger to men of pinching fingers between the rope and sheave wheel. In the accompanying figure is shown a sheave wheel in common use at Fairbanks, Alaska, in hoisting gravel from placer mines, which is simple, strong, and safe.



A WELL GUARDED SHEAVE.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Potash and the Geological Survey

The Editor:

Sir—There appears in *Bulletin* 599, of the U. S. Geological Survey, entitled 'Our Mineral Resources—How to Make American Industry Independent,' a discussion of some of the mineral resources of the United States which require development in order to supply American demand, now that European hostilities have deprived American manufacturers of that source of chemical and mineral materials.

The author of this pamphlet is George Otis Smith, Director of the Survey. Under the title, 'Potash Salts,' I find the following opening sentence: "Outside of Germany, there is no known commercial source of potash salts." This statement appears to be in direct conflict with previous statements made by the Geological Survey, and the readers of your publication will remember that a special bulletin issued, I believe, jointly by the Bureau of Soils and the Geological Survey about two years ago, claimed the discovery by those Bureaus of a commercial source of potash at Searles lake in San Bernardino county, California.

I am willing to concede that Mr. Smith may raise a point as to the specific definition of the term, "commercial source," but regardless of the possible constructions of this term, Mr. Smith does not seem to show a spirit of fairness in this statement. We may lay aside the suspicion that the statement is wilful misrepresentation and assume that it is merely ambiguous. However, I cannot help but feel that the statement is particularly unfortunate in view of the circumstances surrounding the announcement of the Searles Lake discovery, with which, I believe, your readers may not be entirely familiar.

At the time of the announcement of the discovery of potash at Searles lake some two years ago, the owners of the property objected to the claim of the Geological Survey and Bureau of Soils that the discovery was due entirely to the initiative efforts of those departments. The facts of the case are that the presence of potash in large quantities was known by C. E. Dolbear and others some eight months prior to the announcement by these bureaus. The intimation of its presence came to the Geological Survey, I believe, through the misplacement of a copy of a report belonging to the California Trona Co., and shortly thereafter I received a telegram from Frank L. Hess of the Geological Survey, asking that I wire him at government expense full details regarding same. This telegram was referred to C. E. Dolbear, and subsequently Mr. Gale of the Geological Survey and Mr. Free of the Bureau of Soils were taken to Searles lake as guests of the California Trona Co. in the Company's automobile and were given logs, analyses, and other particulars which they confirmed.

Subsequently the special bulletin to which I refer was issued, announcing the discovery of millions of tons of potash at this point and the statement by Mr. Smith at this time would seem to contradict the conclusions reached by Messrs. Gale and Free. It is worth while observing that since this discussion of the authorship of the discovery, the U. S. Geological Survey has either been singularly silent in discussing potash at this point or has passed the subject by with only brief remarks. An instance of this character is the bulletin just published, which makes no mention whatever of the Searles Lake deposits. If the public is to continue to believe in the value and accuracy of the service rendered by the Geological Survey, it would seem that Mr. Smith should issue some statement in this regard.

As I am not materially interested in any way in these deposits, I feel at liberty to call your attention to this matter.

Samuel H. Dolbear.

San Francisco, November 5, 1914.

[The history of the discovery of potash at Searles lake lies in a field of controversy. Whitman Symmes is credited with being the first, in 1898, to recognize the value of the potassium content of the brine. Desiring to get the history straight, we asked him for details, and he has courteously furnished us the statement printed below.—Editor.]

The Discovery of California Potash

I was superintendent for the California Borax Co., which was attempting to extract borax from the sands on the southeastern side of the lake, about two miles from Dean's mill, after the manner of the operations at the Searles works on the northwestern edge of the lake. The California Borax Co. was in operation before I went down there. Its board of directors offered me a lease upon the plant, and while I was superintendent, I made a considerable number of investigations. I rejected the lease, and after making analyses of the water of the lake, I staked out everything that was not owned by the San Bernardino Borax Co. In fact, by mistake, I staked out some of the sodium bicarbonate on the shores of the lake, and Dennis Searles, then manager, became very wrathy. He thought I was jumping some of his claims. I promptly informed him, however, that it was merely an error,

for the reason that I had not seen some of the location monuments, and the incident was closed.

Alfred Von der Ropp has since told me that his people said that the lake had never been staked, and from their standpoint his statement is correct. The only law in force there at that time required that a claim should be plainly marked, so that its boundaries could be determined on the ground. I staked out the entire lake with 1½-in. stakes, with pieces of tin nailed on them. I regarded that as preliminary work and sufficient to hold the ground until I could raise some money. I came to San Francisco and interested a man now living there in the project. In order to satisfy him that I was not mistaken in the value of the brine, I had two complete analyses made by Edmund O'Neil, professor of chemistry in the University of California. I then went to work upon a process for extracting the various salts, and built special filter-presses and centrifugal machines for that purpose.

At that time Borax lake was a long way from transportation, and I was not able to raise sufficient money to proceed with the project. The amount of work required for assessment work alone to hold the property, for one year was enormous. I believed that if I did not take all of the property except that held by the San Bernardino Borax Co. there would probably be competition, and that I would not be able to make any money. I believed that with only one other concern having access to the brine, there was a chance to make something. Finally, after I came to the conclusion that I was wasting my time on the project, as well as the little money I was at that time able to command, I let the whole scheme go by the board. I might add that my friend and I incorporated a company at Sacramento for the purpose of developing the property. Its name was the Crymere Chemical Co., Crymere being a combination for the words standing for clear and crystal.

WHITMAN SYMMES.

Steam Stamps From a Gold Miner's Point of View

The Editor:

Sir—Referring to the most interesting article in your issue of October 3, by Algernon Del Mar, relative to stamp and Hardinge mill installations in the Lake Superior copper district, Mr. Del Mar makes pertinent inquiries which are of interest to metallurgists. In referring to the large installations in the copper districts, he asks "How Mr. Hardinge did it?"

I undertake to answer that question by stating that my preliminary investigations tended to prove that the Hardinge mill was more efficient that the Chile mill, based upon results obtained in crushing the metallic silver ores of Cobalt. Tests were made of $\frac{3}{16}$-in. jig tailing from the Lake copper district sent to New York for testing in Hardinge mills, with the result that we knew our position, and later sent one of our mills to the Calumet & Heela plant on trial. A contract was made with the Calumet & Hecla Co., based upon the results obtained. The long tube-mill, cited by Mr. Del Mar as being 4 by 26 ft., is in reality 5 by 18 ft. and was installed alongside of the Hardinge mill; Chile mills were already in operation. These three classes of machines were run in strict competition and on identical feeds for over a year. The Hardinge mill was only 22 in. long, in the cylinder, and produced less oversize than did and does the 5 by 18 ft. cylindrical tube-mill.

The result of these combined tests was the selection of the Hardinge mill. Further competitive tests were made by still other companies in this district, resulting in the construction of one plant of 64 8-ft. mills, another plant of 42, and others of less numbers. Plans are now completed which call for two more plants, one of which will contain 32 8-ft. and the other 12 8-ft. Hardinge mills.

Mr. Del Mar says that only one of the users of the Lake district thought conical mills had any appreciable sizing action. If the cones are of no value and have no classifying effect, then the Hardinge mill of only 18 to 22-in. cylindrical length has some unknown good reason for its being. After exhaustive trials in competition with a tube-mill as well as Chile mills, the Calumet & Hecla Co. selected the 18-in. cylindrical length of mill for the grinding of over 40,000,000 tons of tailing. One can hardly question the action of a company whose experience has enabled them to pay over $120,000,000 in dividends.

Mr. Del Mar states that the flattening of the particles of copper in pebble mills causes them to float off on the table, which would not be the case with a machine giving a cylindrical or spherical shape to the copper particles. In this assertion he is mistaken. Originally and theoretically, I also supposed such would be the case, but the actual practical working gives data showing the contrary. The results proved that the Hardinge mill effected 25 to 33% higher saving than did the Chile mills, the product of which was more or less granular and by no means flattened, when compared with that of the Hardinge mills. An explanation of this unexpected result, given by one superintendent in the copper district, was to the effect that the copper scales, through natural attractive cohesion or possibly skin friction, lay one upon another like scales on a fish, forming a flat mass on the Wilfley table. The Chile mill product, however, consisted of small spongy and rounded particles which were more readily carried away by the wash water flowing over the table. This same flattening effect also occurred in crushing metallic silver ores in the Cobalt district in Hardinge mills, and to this I attribute the unusually high saving obtained in many plants of that district.

The exhaustive critical investigations in the Lake copper district are the result of necessities developed by over 60 years' experience and experiments with all kinds of grinding devices, and we certainly must give them credit for intelligent impartiality in their conclusions. It is well enough for the layman to question the reason for certain physical actions, but the result—economic

efficiency—certainly must be considered as being superior to a mere supposition based on theory.

I am enclosing two samples of copper concentrates both sized through 40 on 60 mesh, from which it will be seen that the physical conditions are as above stated. You will note that the Chile mill product is partly rounded while that of the Hardinge mill is a mass of scales. The one on the left is the concentrate from Chile mill crushing, while that on the right is the concentrate from Hardinge mill crushing.

H. W. Hardinge.

New York, October 26.

[This interesting letter has been delayed in an effort to get satisfactory photographs of the two samples of concentrate forwarded with it. Nothing suitable for publication has proved possible, but we can state that the difference in shape referred to is very marked. While the two samples have been sized on the same screen, because of the difference in shape of particles the Chile mill product *looks* decidedly finer.—Editor.]

Trade Possibilities in Latin America

The Editor:

Sir—In further elucidation of your editorial in the *Mining and Scientific Press* of November 21, as far as Bolivia is concerned, I beg to mention that the petroleum, crude and refined, found at the ports of Chile comes from two different sources—from the north of Peru and from California. Gasoline and the residue from oil refineries also find there a ready market. The Standard Oil Co. of California has established at all the principal ports, large storage tanks, replenished by its tank steamers. Either by a submerged pipe or a flexible pipe-line supported by floating skids, as we have them in connection with suction dredges in San Francisco bay, the oil is pumped from the ships to the shore tanks and from these is drawn off to railroad cars to be conveyed to the various points on the railroad systems of Bolivia. The ports of Arica and Antofagasta are thus equipped.

The Standard Oil Company's work is finished when the oil is delivered to the large shore tanks, while the distribution of the oil to all inland rail points rests with W. R. Grace & Co. This Company has its principal Bolivian office at La Paz, and a great number of agencies in all parts of the country. There are oil prospects in various parts of Bolivia, but no development work has been performed in connection with any of them; besides that, these prospects are at remote points, with no good connections. No doubt they will come in with advantage in the future.

Steam boilers in Bolivia are always a serious consideration, on account of first cost, transportation, operation (especially at high altitudes), repairs, the water supply (which may have to be procured from considerable distance), and other local difficulties. Where no boiler is required, as where petroleum is directly converted by a Diesel engine into power for mechanical purposes, or into electric power for transmission and subdivision, these problems are greatly simplified.

In ordinary times the cost of one ton of 2240 lb. of coal at the Pacific Coast ports on board steamer is $7, and of petroleum $10, in round figures. Bolivia offers a field for investment of capital in many lucrative enterprises. Experienced engineers, able and reliable, can be found, ready to take a hand in the installation of mines, mills, and other metallurgical enterprises.

G. W. Wepfer.

Berkeley, California, November 24.

Precision of Thought

The Editor:

Sir—In a late issue you laid down the rule that "* * * 600,000 tons *was* crushed" was the proper form. I decidedly object, and state my reasons in a few brief words.

1. A fundamental rule of grammar, "plural noun—plural verb." If this rule is not strictly binding, then there is no rule whatever in grammar, from cover to cover, that is worth anything at all. If you can override this, then you should hereafter sign yourself as "*Dei gratia Rex Gram.*"

2. In order to reach your conclusion, you assumed that the words of the sentence did not mean what they said, "tons," but meant something else. You are out of place. There is only one human that is allowed to talk such nonsense, and that is the judge on his bench.

3. You claim that the study of such nice hair-splitting technicalities must increase "preciseness of thought." I lift a warning finger, for the prolonged study of the vacuities of the fourth dimension produces minds that are unfit for ordinary life, and we have to build asylums for them.

On the contrary, I implore you to urge your readers to persevere in the effort to think real thoughts—valuable ideas—and prayerfully to avoid the temptations of metaphysics and Lindley Murray.

4. The chief curses of our schools for children are the various kinds of trash, of which the alleged 'grammar' is the worst. The permanent effects of the printed grammar are little deeper than the shadow of a passing cloud. The makers of a language are the common people, and the dominant force is the *ear;* it is the *ear* that makes all meters and rhymes, and all poetry and prose that will live.

W. S. Prosser.

San Jose, California, November 16.

[This letter illustrates what we stated editorially—that many confuse form and fact when using collective nouns. Whether plural or singular verb should be chosen depends upon what the writer wants to say, as we illustrated. English has many pitfalls. There are numerous instances where the verb, even when singular in fact, follows a plural form of noun and conforms to it in form, but collective nouns allow discrimination to be exercised.—Editor.]

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

HYDRAULICKING in Alaska shows a duty of 5 cu. yd. of gravel per miner's inch per 24 hours.

LEAD ORES from the Coeur d'Alene mines, and sent to the East Helena smelter, contain from 10 to 13% sulphur.

EMPTY DYNAMITE CASES which show stains of exuded nitroglycerin generally explode when burned, and should never be used as fuel. In lighting them it is safer to lay a train of fuse or waste two or three feet long.

FERBERITE is a mineral of the wolframite series which is composed wholly or in great part of iron tungstate. It is comparatively rare, generally occurring in small deposits, but in Boulder county, Colorado, it occurs in commercial quantities.

A SHAFT-SINKING RECORD was recently made at the Coker mine of the Mineral Point Zinc Co., near Livingston, Wisconsin, when one man working one shift sunk a 5 by 8-ft. hole 60½ ft. in 42½ days in limestone. The consumption of powder was 250 lb. of 35 Du Pont Red Cross Extra brand.

AN AERIAL TRAMWAY is used to convey copper ore from the Britannia mine, in British Columbia, to the concentrating plant. The former is at an elevation of 3275 to 3775 ft., and the latter at tidewater, a distance of 3¾ miles. A Leschen patent special automatic ropeway, in two sections, carries the ore. It operates by gravity at a speed of 300 ft. per minute, and has a capacity of 40 tons per hour, using 10.5-cu. ft. buckets. A flattened strand cable is employed for both the track and traction ropes. One rope handled 400,885 tons of ore in 682 days.

WASH-HOUSES are to be erected at Illinois coal mines by the operators, in compliance with the state law. The estimated expense of construction is as follows:

Man capacity.	Building.	Equipment.	First aid, etc.	Cost per man.
300	$3971	$1933	$1431	$24.45
600	5904	3047	1431	14.90
1000	8308	3727	1431	12.45

The fixed charges on a wash-house of $10,000 cost would be about $200 per month, not including water, steam for heating water and radiation, and insurance.

IN TREATING GOLD with nitric acid, none of the gold should go into solution, unless the acid contains chlorine as an impurity, or some salt is used which would generate chlorine with the acid. It is improbable that any gold could go into solution, since gold is not soluble in nitric acid. Solutions of this acid containing gold must first be boiled to dryness to get rid of the acid. If litharge or some other form of lead is added, the dry residue can at once be melted, and the gold precipitated with the lead. If it is desirable to dissolve the gold chemically, digest the dry residue with hot water, and precipitate the gold with oxalic acid or ferrous sulphate.

EXPLOSIVES are not manufactured in Australia to any extent, and during 1913 imports were as follows, including gelignite, dynamite, and other nitroglycerin compounds, and sporting and blasting powders: Western Australia, 3,309,005 lb.; New South Wales, 3,154,145 lb.; Victoria, 1,487,556 lb.; Queensland, 1,227,239 lb.; South Australia, 1,728,860 lb.; and Tasmania, 452,400 lb.; valued at £609,375. In the first-named state 2,006,970 detonators, and 247,500 coils of fuse were imported. In 73 private and 5 government magazines of this state there is a capacity for 1092 tons of explosives. There were 1655 tests made during the year.

PEARL is a lustrous calcareous concretion, chiefly calcium carbonate, deposited around a central nucleus in successive filmy layers of a nacreous or mother-of-pearl substance. Pearls found in the oyster are believed to be the result of an abnormal secretory process caused by an irritation of the mantle of the mollusk or oyster. Early in October, at Broome, Western Australia, a gem was found in a blister in the adductor muscle of a 5-lb. mother-of-pearl shell, at a depth of 48 ft. in the sea. The blister was 1¼ in. long, 1 in. wide, and ⅞ in. high. On being opened, it was found to contain a perfectly round pearl of 100 grains, which was cleaned down to 96 grains. If it can be properly cleaned and retain its shape, it will be worth £8000 or $38,400.

LOCATION of claims by an employee raises questions, but we know of no objection to the employees of a mining company making locations in their own name and for their own interests, provided they are not made in the regular course of their employment or because of peculiar knowledge as to the character of the ground located, gained through such employment. In other words, if the location is made out of working hours and under knowledge of conditions not gained through any fiduciary relation to the company, such location would enure to the benefit of the employee and he could not be held as trustee for the company. The idea is that the location should be made distinctly outside of the scope of the employment or knowledge gained by reason thereof.

MINING IN THE FAR NORTH*

The Upper Yukon: Circle City, Eagle, and Woodchopper

By EMIL EDWARD HURJA

The Circle Mining District

The discovery of gold on Fortymile creek was made in 1886. Later discoveries in the Birch Creek and Rampart districts, in 1893, encouraged and stimulated the development of placer mining on all streams entering the upper Yukon. Circle was founded by miners from the Fortymile coming down the Yukon to the so-called Birch Creek diggings. Circle is 140 miles below Eagle.

There are several stores there, one of the biggest being that conducted by the Northern Commercial Co. There is a wireless station, which connects with the Fairbanks station, as well as with Eagle. A post-office, several residences, and a roadhouse make up the rest of the camp.

A good road connects Circle, as the local supply point of the mining area surrounding it, with the different creeks. Three roadhouses, Twelvemile, Central House, and Miller House, are maintained at convenient intervals along the trail.

CIRCLE CITY, ALASKA, FROM THE YUKON.

The headwaters of Crooked creek occupy a fan-shaped area within the edge of the hills to the south of its broad, flat valley. On its meandering way eastward to Birch creek, it receives also two tributaries, the Boulder and the Deadwood, which head a dozen or more miles to the south and flow northeast to the main stream in parallel courses about three miles apart. The creeks that are of economic importance on the north side of the divide are Deadwood, Mammoth, Mastodon, Independence, and Miller; on the south side, Eagle creek, and its tributary, Mastodon fork. Deadwood creek is about 20 miles long.

Season of 1914

The summer of 1914 was a good one for the Circle district. The output for the season is expected to be over $250,000, which exceeds any year since 1907. Water conditions were excellent; the heavy rains that kept up during the entire summer maintained the ditches at their high mark for the whole sluicing season.

The Risdon dredge which was erected early in 1912 on 10 Above, Mastodon creek, by the Mastodon Creek Dredging & Hydraulic Co., has been dismantled. Its operation was not satisfactory, because of the age of the machinery. The dredge was the first brought to the Klondike and was moved from Dawson to Circle in 1911. The ground held by the dredging company has reverted to the original owners, and the claims from 10 to 17 Above, inclusive, are being operated by hydraulic methods. Theron Feil and J. P. Anderson are conducting hydraulic operations on the ground, one plant on 10 and the other on 20 Above. Anderson owns from 18 to 24 Above, inclusive. A. P. Clark owns considerable ground on upper Mastodon, including claims 29, 40, and 41 and 52 Above. He erected a hydraulic plant last year, but was unable to do any work until the present season.

Berry & Lamb Dredge

Barnette & Harington own from 8 Above to 5 Below, Mastodon. They operated the past summer on Discovery. Berry & Lamb, on Mammoth creek, from the mouth of Mastodon to one and one-half miles below the mouth of Porcupine creek, are hydraulicking. A dredge will be built on the ground during the winter, to replace the hydraulic plant. The material was landed at Circle during the summer by boats of the American-Yukon Navigation Co., and will be freighted 40 miles over the government road to Mammoth creek. The dredge was built by the Union Construction Co. of San Francisco, California. The buckets have a capacity of 3½ cu. ft. Power will be furnished by two 85-hp. Wolf locomobiles. Wood will be used for fuel. It costs $10 per cord and is hauled from Porcupine creek. The ground on Mammoth has a depth of from 12 to 14 ft. The construction of the dredge will proceed during the winter.

On Miller creek, a tributary of Mammoth, J. P. Anderson, Jay Kelly, and Charles Lamb are operating.

Kalenborn & Moss spent the summer preparing to experiment on Independence creek with a new type of gold-saving apparatus. They have purchased a Bucyrus one-yard steam-shovel which had been used in stripping work on the Mammoth Creek holdings of C. J. Berry and Charles Lamb, and with a movable grizzly over portable sluice-boxes expect to mine economically. The Kalenborn-Moss ground is one mile from the mouth of Independence.

Clarence J. Berry has a hydraulic plant at work on Eagle creek, a tributary of Birch creek. The ground is from 14 to 24 ft. deep. Water is obtained from Independence creek. From two to four nozzles are used, depending on the water supply.

Deadwood Creek

From eight to ten small outfits are 'shoveling in' on Deadwood creek, a tributary of Crooked creek. The ground is shallow and of comparatively low grade, so that it pays to work in primitive fashion. Ground on the lower end of the creek is 'drifted' in the winter.

Riley Erickson and William Arthur are drifting on Switch creek, a tributary of Deadwood creek.

*[Previous articles in this series by Mr. Hurja on mining in Alaska and the Yukon have been 'Mining Revival in the Ketchikan District, Alaska,' July 4; 'Wrangell, Alaska,' special correspondence, July 11; 'Developments of the Alaska Gold Mines Co.,' July 18; 'Juneau, Alaska,' special correspondence, July 25; 'Cordova, Alaska,' special correspondence, August 8; 'Valdez and Prince William Sound,' August 15; 'Seward and the Kenai Peninsula,' August 29; 'The Koyukuk Mining District,' September 12; 'Operations of the Yukon Gold Co.,' October 10; 'Skagway-White Horse Mining District,' October 17; 'Operations of the Canadian-Klondyke G. M. Co.,' November 14; 'The Klondike, the Treadgold Placers, and Outlying Districts,' November 28.—Editor.]

Anton Sather landed a hydraulic plant at Circle this summer and will have it hauled over the trail to No. 3 Switch creek, where it will be erected. He owns No. 3, 4, 5, and 6 on Switch. The ground is from five to seven feet deep. The outfit consists of 1500 ft. of pipe and one No. 1 Hendy nozzle. J. Stack, owner of several claims on upper Deadwood creek, plans to erect a hydraulic plant soon. Jack Cotter, who worked on upper Switch last year, may continue work next season. On Half Dollar creek, a tributary of Harrison creek, Lind & Co. worked during the summer. Recent finds of paydirt have attracted considerable attention to the district. E. H. McGriff, said to represent outside capital, recently completed an examination of ground on lower Deadwood that appeared feasible to dredge.

Eagle District

The Eagle district embraces a few streams flowing into the Yukon near the town of Eagle. Eagle is the first port on the Yukon from the Yukon boundary. It formerly was a military post —Fort Egbert—but that has been abandoned. There is a store, a post-office, several trading posts, and a roadhouse there. U. G. Myers is United States commissioner and recorder.

There are five outfits at work on American creek, which enters the Yukon 10 miles from Eagle. Curtis & Danielson have a crew of from eight to ten men employed, as have A. H. Meinzer and August Fritsch. Meinzer is on the main stream. Fritsch is immediately above him on the same creek. There are a few smaller outfits farther down the creek. Most of the work is open-cut. The creek was discovered in 1894 and has been worked intermittently ever since. Several years ago a $135 nugget was picked up on No. 8 Below, American creek.

The Seventymile District

The work in the Seventymile district in the upper Yukon district of Alaska during the summer has been encouraging, despite the fact that the production is small compared with other Alaskan camps. Water conditions were favorable and indications were that the output would be greater than last year. Seventymile river is a tributary to the Yukon, entering on the left limit 20 miles below the town of Eagle.

Froelich & Kummer, operating on Crooked creek, a tributary of Seventymile, expected their season's work to net between $5000 and $6000. William Russell is working on the main river at the bar near the falls of the Seventymile. His operations have been entirely satisfactory. Olson & Johnson and Jones & Hanson are two open-cut outfits on Barney creek, which operated satisfactorily because of the abundance of water. Each expected to clean up $5000 to $7000. Turnbull & Williams erected a small hydraulic plant on Barney creek and expected to do considerable dead work, preparatory to a better season next year. They estimated this season's output at $6000.

C. F. Yost is operating on Nugget creek, in the Seventymile precinct. Ross & Madison and James Murphy operated on Alder creek. The ground they worked by open-cutting had a depth from 6 to 14 ft. E. A. Robertson's work on Flume creek probably is the most pretentious placer mining in the district. He has a small sawmill operated by water-power. His mining is conducted on a high bar having a depth of from seven to eight feet. He has built automatic dams to control the water, and although this season's work was satisfactory, he hopes for better returns next season.

Minor prospecting work has been done on Washington, Sonickson, Fox, Curtis, and Pleasant creeks. Some 'sniping' has yielded small returns. There is much low-grade ground on Seventymile that has been subject to investigation by different mining engineers.

There is but one quartz prospect in the Seventymile district. It is known as the Caribou and is on Flume creek, a tributary of the main Seventymile. An adit 100 ft. long has been driven on it and an arrastre erected to sample the ore. The vein is said to have a maximum width of 80 ft. Hudson brothers have found coal prospects at the head of Charley river, 100 miles from the Yukon.

TAKING WOOD ON A YUKON STEAMER.

Woodchopper Creek District

Placer mining continues in the Woodchopper Creek district of Alaska. Most of the operations are on a small scale and of the pick-and-shovel order, although plans are under way for a hydraulic plant. There are about 20 men at work in the district, most of them on Coal creek, a left limit tributary of the Yukon entering it 60 miles above Circle.

Nelson & Beaton are working a crew of five men on Coal creek. George Powers and Frank Slavin have a hoisting plant and expect their season's output to be doubled over that of last year. On Woodchopper, John Holstrom, Frank Bennett, Valentine Smith, and Fred Myers are working on a small scale. Chris Gabelman is operating a small plant. Jack Boyle and Charles Boyle are taking out a small block of ground this year. Water conditions on Woodchopper have been fairly good during the past summer.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

Camp Bird and Messina Affairs.—Mexico Mines of El Oro Lead Producers and Consumers.—Copper Exports.

The Camp Bird company reports that its estimated profits for the quarter ended September 30 totaled $139,000, from 7843 tons of ore treated. To this must be added about $75,000, the estimated proportion accruing to the Camp Bird from the Santa Gertrudis, of which the profits for the month of October alone are estimated at $60,000. F. H. Leslie, chairman of the board of directors of the Messina company, operating in the Transvaal, in which the Camp Bird also has an interest, made a statement at the annual meeting of that Company in London recently, in which he defined his position and that of H. C. Hoover toward the action taken by the board before they joined it in June last, on the collapse of the enterprises under-

TAPPING COPPER MATTE, MESSINA MINE, TRANSVAAL.

taken by J. P. Grenfell. He also estimated that the Messina would make profits of $250,000 or over next year, and explained that an attempt would be made to sell 200,000 of the 5-shilling ($1.25) reserve shares for 10 shillings ($2.50) per share in order to provide £100,000 more working capital. Mr. Emery has been appointed as general manager at Messina. During the year ended June 30, 1914, the mine produced 73,190 tons of ore, of which, after sorting, 58,812 tons was milled. This gave 9965 tons of 10.7% concentrate and 743 tons of 58% copper matte. The profit was $290,000. Ore reserves are estimated at 252,000 tons.

The Mexico Mines of El Oro Co. reports that mining and milling has been resumed on a small scale, only development being done since April last, and the machinery overhauled.

Lead, ordinarily one of the most featureless of metals, has advanced in price recently, as good orders have been received here from Russia, and some metal has also been shipped to Italy. It is interesting to notice that the American Smelting & Refining Co. is the largest producer of lead, with an output of 225,000 tons per year, while the Western Electric Co. is the largest buyer, taking about 62,500 tons of the metal yearly. The other principal producers are the St. Joseph Lead Co., with an output of 75,000 tons; the United States Smelting, Refining & Mining Co., 30,000 tons; International Smelting & Refining Co., 30,000 tons; Balbach Smelting & Refining Co., 25,000 tons; and National Lead Co. The chief consumers are the General Electric Co., United States Steel Co., Standard Underground Cable, and National Conduit & Cable. Of course the manufacturers of white lead and lead pipe are large consumers as well. The St. Joseph Lead Co. announces that after the first of the year it will produce corroding lead.

Copper exports from New York for the last three weeks of October are given as 11,606,369 lb., over one-half of this being consigned to Genoa. Exports have climbed back so near to normal that the toll figures for October only represent a falling off of 13%, compared with the same month of last year; but the lower price realized corresponds to a decrease of over 33% in value. Increased domestic demand has resulted in sending the price of the metal upward during the past week, and no check of the upward tendency is yet visible. The dispatch of the shipments to Europe is still hampered by the reluctance of the steamship companies to accept copper as cargo, and of the insurance companies to issue policies on it; but aside from these difficulties, export conditions seem to be improving, as through the efforts of the State Department nearly all the neutral countries of Europe have given guarantees as to re-exports of copper, which are apparently technically satisfactory to England, though they do not yet operate to prevent the detention of ships.

HOUGHTON, MICHIGAN

Iron-Ore Districts to Be Represented at the Panama-Pacific Exposition.—Smith Mine.—Winona Leased.—'Copper Handbook.'

The iron-ore districts of the Gogebic, Menominee, and Marquette ranges of Michigan, and the Mesabi and Vermilion ranges of Minnesota are to be represented at the Panama-Pacific Exposition at San Francisco by exhibits by the U. S. Steel Corporation. Walter W. J. Croze of the Oliver Mining Co., a subsidiary company, is gathering the samples and arranging them at Duluth. The exhibits will include mining the ore, transport from mines to ore docks, an ore dock, model of an ore steamer, and transport to the furnaces. Also a reproduction of the Alpena mine at Virginia, a relief map of the Lake Superior iron district, a painting of the Pittsburgh Steamship Co.'s fleet, and many other illustrations connected with the industry.

About the first of November there was published in the local press a statement that the diamond drilling on the Smith property, about nine miles southwest of the White Pine, showed fair results. Since several inquiries have been made as to how much drilling was done, and by whom, it might be well to correct this statement. The exploration work done on this property consisted of cleaning out some old pits sunk about 40 years ago, and sampling and assaying the rock. This is stained with copper, and thin seams of soft malachite, containing in some cases cores of native copper, run through the rock. A winter supply road is being cut to the locality, and a winter camp built. No diamond drilling has been done so far, and probably will not be done until spring, unless further exploration warrants taking in a drill during the winter.

When the Winona mine was forced to suspend operations,

John Broan, the mining 'captain,' leased the mine from the Company and began working on tribute. It is reported that by careful sorting underground, the 'rock' now being mined will average 22 lb. of refined copper per ton. With 30 men underground and 10 on surface, five cars of 'rock' per day are shipped to the Centennial-Allouez stamp-mill. In order to employ as many men as possible, Mr. Seeber, the superintendent, has a number of men cutting timber on Company land. The hardwood is sent to the Stratton handle factory at Atlantic.

'The Copper Handbook' will no longer be published in the Michigan copper district. This well known publication on copper was founded in 1900 by the late Horace J. Stevens, of Houghton, and was published annually by him until his death in April 1912. About a year later, rights of the book were sold to Walter Harvey Weed. Mr. Weed, as owner and editor, opened an office in Houghton, and published the 1914 edition. It was feared at the time of the sale that Mr. Weed would not maintain an office in Houghton for any length of time. However, the news of the removal of the publication office to New York is received with much regret by the people of the copper country. Mr. Weed desires to handle all his business interests from one New York office, and the Houghton office of 'The Copper Handbook' will be closed about December 1.

LUNING, NEVADA

CONDITION OF THE DISTRICT.—LUNING-IDAHO, COMMERCIAL, RED BUTTE, SHIPPER, AND WAGNER.—AZURITE COMPANIES.—GOLDYKE DISTAICT.

Generally speaking, the future of this copper-silver district appears bright. Although the copper properties are slow in getting under way again, yet the district is working at about 75% of its average mining capacity. Success of the improved leaching processes on the ore found here has caused a continued activity in mining this metal. This, with the fact that the gold and silver contents are high, makes the district a good one at this time.

The large holdings of H. H. Hill and C. Barr of the Nevada Silver Peak have been financed by Frank Everett and associates, who will erect a mill on the ground at once. This property, which is about eight miles northwest of Luning, consists of four claims having a series of well defined veins varying from 2 to 46 in. wide, and averaging $16 to $22 gold per ton. The mine has been worked in such a manner as to prove a large body of ore which will insure the erection of a small mill, and the further development of the property.

The Luning Idaho Mining Co. is going right ahead with a small force, and extending development on the eastern portion of the ground and has cut large bodies of good grade copper ores, some of it containing over 80 oz. silver and some gold.

The Commercial Ores & Mines Co., which has taken over the Luning Gold Mines Co.'s holdings, will soon be ready to increase its output and develop this ground. From reports received, the outlook there is for another large shoot of high-grade ore, such as the Luning people had two years ago.

The Red Butte Mining Co., which is operating west of town, has opened good ore in the adit which is being driven by C. S. Smith, and this will insure steady operation during the coming winter. This Company, which is composed of Spokane people, has made arrangements to start sinking on the new ore at once.

The Shipper Copper Co. and Alameda Mines Co., which are working on a custom leaching plant to treat a large tonnage of ore, have plans nearly arranged for the beginning of preliminary work to start December 1.

The Wagner-Azurite Co., which closed down to permit installation of the flotation process in connection with its mill, will make arrangements to be running full time again by January 1.

The continued activity in gold mining has again brought the Goldyke district north of Luning to the front, and in the past week several leases were given on good property, and long delayed work was started on others. Also there has been a quiet movement of mining men out there, which should lead to the general opening of a rich mineral belt. This district will be much heard of during the coming winter.

Summing up the general conditions in southwestern Nevada, the opinion is that it is entering a new era of mining, of which the Luning area will draw a large share of attention.

SILVER CITY, NEW MEXICO

ZINC MINING DEVELOPMENTS.—CHINO COPPER IMPROVEMENTS.—MOGOLLON MINES.—MINING PATENTS.—SIERRA COUNTY PROSPECTS.

Work was commenced, on October 16, on Thunderbolt mountain, near Hanover, by the Empire Zinc Co., in developing another zinc sulphide orebody. A two-compartment shaft will be sunk. The Company has already opened large carbonate of zinc ore reserves west of Hanover, and is making periodical shipments to Kansaa and Wisconsin. If the blende claims are operated, the erection of a concentrating plant will be necessary. All Hanover ore being mined by the Company occurs as a replacement in crystalline limestone. C. T. Brown, manager for the Company in New Mexico, would make no definite statement as to the actual plans of the operators, but it is generally understood that extensive construction work will be done at both Hanover and Pinos Altos, where zinc property is owned.——At Fierro, several promising zinc claims are being developed under lease and bond.——J. W. Bible is taking out a good grade of zinc-lead ore and opening some carbonates.——T. B. Fisher and associates have established a camp near the McGee mines, and intend opening up the zinc sulphide orebodies. It is claimed that their intention is to erect a small treatment plant in Shingle cañon, after doing experimental work.

The Chino Copper Co. is experimenting with a flotation process in its mill at Hurley, and has a unit at work treating slime. Several additions have been made to the mining forces at Santa Rita, and a shovel is now digging in the northwest cut. The new crushing plant and loading station at Santa Rita is being operated with a great saving of time at the concentrator, all ore now being under 2 in. when it reaches the rolls. The plant is situated at the west end of Santa Rita and on the side of a dump. The ore is dumped from ore-cars down a concrete chute about 50 ft. wide and 100 ft. long, in which grizzlies are arranged. Jaw crushers reduce the coarse, and all the ore is elevated across a small *arroya* to the steel loading bins, where it is deposited in three piles from both sides of the bins in Santa Fe cars *en route* to Hurley. The Company is making needed road improvements on Santa Rita hill. Drilling for air is in progress at the old Santa Rita mine.

In Mogollon, work is progressing at the usual rate in all mines and mills, although it is reported that the Deadwood mill was closed down last week for repairs and renewals.—— The Socorro Mining & Milling Co. has the towers up for its 2000-ft. tramway across an *arroya*, and it will soon be in use. The Company shipped 16 bars of bullion to New York on November 8.——The Ernestine Mining Co. shipped 15 bars on November 9. Frank Hitchcock, ex-postmaster general, president of the Company, is spending some time in the vicinity.

Mining patents are being secured this year by the Fauquier company (C. Amory Stevens), of New York, on property in the Pinos Altos, Chloride Flat, and Burro Mountain districts; Woodward Mining Co., of Tyrone, New Mexico, on its property in the Little Burros consisting of 11 claims; the Azure Mining Co., on Burro Mountain property, and other small property holders. Quite a lot of patent applications are

listed from Mogollon. Throughout the district assessment work has been postponed owing to the exemption bill being before Congress.

In the Organ district of Dona Ana county, lessees of various properties are shipping a good grade of copper-silver ore to the El Paso smelter.——Lois A. Wright, of New York City, will examine some property in the district soon.——Norvel Welsh, lessee of the Memphis mine, has just returned from New York.——J. C. Miller and S. Brown are reported to have closed a lease on the Leona mine, and have begun sampling. ——J. A. Yawger is in charge of two assessment crews in the district.

Sierra county is in the limelight at present, its most promising districts having been examined recently by prominent engineers, and reports are being compiled.——It is claimed that a leaching plant at Kingston is one of the proposed projects.——The Carpenter zinc-copper-lead district is receiving its share of newspaper publicity, but active work has not started. Owen Bros., of Santa Rita, have become heavily interested in the area, and are preparing to operate some good property.——The Calumet Commercial Mining Co., at Phillipsburg, is working the Republic group and treating good grade ore.——There is much property in Sierra county worthy of examination.

TORONTO, ONTARIO

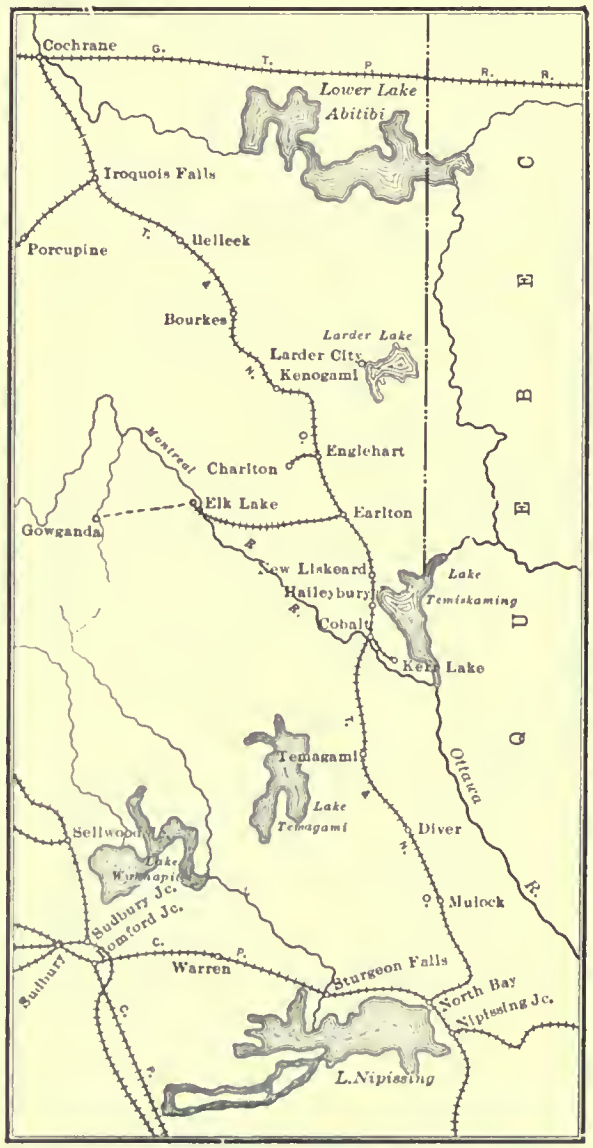
SHARE DEALINGS ON 'CHANGE.—CROWN RESERVE AFFAIRS.—SILVER OUTPUT FOR NINE MONTHS.—NICKEL.—NOTES ON THE DOME, HOLLINGER, JUPITER, TOUGH-OAKES, AND SESIKANIKI DISTRICT.

Business at the Mining Exchange, which has been very quiet since August, is beginning to improve. Two sessions daily are now held in place of one, and the minimum price limitation has been removed with but little effect on quotes, the only restriction now in force being that all transactions must be for cash. The most noteworthy price change was in Crown Reserve, which sold down to 68c. as the result of an official announcement that the present dividend rate of 24% would be reduced. No intimation as to the extent of the reduction is given, but the general expectation is that the dividend will be fixed at 12%, payable quarterly, instead of monthly as at present. The Company is in an excellent position, having ore reserves of about 2,000,000 oz. and a surplus on hand in the neighborhood of about $900,000; but the directors are disposed to pursue a conservative policy in connection with the acquirement and development of new properties. The Porcupine Crown is turning out a valuable asset, and also the Silver Leaf, in which a vein 1 in. wide of high-grade ore has been cut at the 75-ft. level.

The returns to the Bureau of Mines for the first nine months of the year show a heavy reduction in the output of silver, compared with last year. The production was 19,448,018 oz., valued at $10,082,229, a decrease in value of $2,885,710. The output of nickel was 18,085 tons, valued at $4,023,556—an increase of $197,923.

Notwithstanding the recent issue of an Order-in-Council prohibiting the export of nickel to most of the European countries, a feeling prevails that Germany may still be drawing supplies of this metal from Canada *via* the United States, and more drastic measures are being strongly advocated. It is pointed out that no nickel is exported anywhere from Canada except in the form of matte, which is refined in the United States, so that the action of the government entirely fails to meet the case. The question is likely to come up at the next session of Parliament.

The Dome mine has now six years' ore reserves blocked out at the present capacity of the mill.——The main vein of the Hollinger has been cut in the winze at the 800-ft. level, where it shows about the same width and value as on the upper levels. A third compressor with a capacity of 50 drills is being installed, and is expected to be in operation by the end of the year. The cross-cut to connect the new main shaft with the Miller-Middleton has been commenced, and will be carried 800 ft. from the present workings to the old Miller-Middleton shaft.——At the Jupiter, 500 ft. of the main vein has been opened at the 400-ft. level, and 225 ft. at the



MAP OF PAINCIPAL MINING DISTAICTS OF ONTARIO.

475-ft. level. The option of the McKinley-Darragh mine expires December 17, and the final examination and sampling will be made shortly.——Development at the Tough-Oakes has reached the 300-ft. level and the veins are reported better than at the surface. It is stated that the ore assays about $500 per ton.

Eight locations in the Sesikaniki camp, situated on the east side of Wolf lake, Maisonville township, known as the Murray, Mogridge & Powell group, have been bought by J. M. Bell of the Huronian Belt Mining Co. The price is stated as $150,000.

The Caribou-Cobalt company shipped 52,833 oz. silver to England last week.——A rise has been started from the 330-ft. level of the Hudson Bay south workings, to reach the conglomerate.

The main vein of the Hollinger is being opened at 800 ft. Early next year the electric haulage system at 425 ft. will be ready.——Cross-cutting at 675 ft. has been started in the Acme. Three veins have been cut at 550 feet.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Circle

W. J. Julian, D. Creighton, and John A. Clark are financing a hydraulic plant on Woodchopper creek. A ditch which will have a length of 5½ miles is under construction. It will be supplemented by two pipe-lines, one 800 ft. and the other three-quarters of a mile long. Water will be conducted from Iron creek to the mouth of Mineral creek. The ground on Woodchopper creek is from 9 to 18 ft. in depth, all of which is gravel.

Juneau

During October the Alaska United company results were as below:

Details of operation.	Ready Bullion Claim.	700-Ft. Claim.
Stamps working	120	120
Ore crushed, tons	20,132	21,315
Concentrate saved, tons	496	448
Total gold recovered, realizable value	$44,951	$48,186
Average yield, per ton	$2.25	$2.28
Operating expenses	$27,950	$35,857
Construction	$4,878	$8,988
Net profit	$12,123	$3,341
Development, feet	152	884
Stock of broken ore, tons	+3,120	+13,380

The report that the Jualin mine was closed for the winter was incorrect, according to the manager, A. N. Nadeau. Some machinery was due to arrive at Juneau last week for the property, including a Diesel engine.——The sum of $250,000 is to be spent in developing the Kensington mine, controlled by D. C. Jackling and B. L. Thane. Two parallel lodes show a good body of ore. B. B. Nieding is mine superintendent. A 500-ton mill is proposed for the future.

Nome

A violent storm is raging at Nome, and ice from the Bering sea is being forced against the town, while several mining areas nearby are surrounded with water. Solomon, 32 miles east, is also flooded.

ARIZONA

Cochise County

The Calumet & Arizona property at Bisbee was inspected last week by T. F. Cole, of Duluth, and Charles Briggs and C. E. Briggs, of Calumet. They will also inspect the New Cornelia mine in the Ajo mountains.——Good results are being made in developing the Shattuck-Arizona mine. Between the 100 and 300-ft. levels a large tonnage of $15 gold-silver ore has been blocked out. Good copper ore is showing at 400, 600, and 800 ft.——Work on the gold-bearing area of Juniper Flats continues with encouraging prospects.

Gila County

On July 17, 1913, the Inspiration Consolidated Copper Co. of Miami, commenced a suit against the New Keystone Copper Co. to condemn a right-of-way for an underground tunnel through the latter Company's Copper Hill mining claim. The object of this was for the transport of ore mined by the former Company from its Live Oak claims, to the working shafts of the Inspiration claims, and through these to the surface. The Inspiration started driving the tunnel, but the Keystone obtained an injunction from the Superior Court of Gila county stopping further work. Then the Inspiration started the suit of condemnation under the right of eminent domain for such purposes. The Inspiration and Live Oak mines contain 30,000,000 and 15,000,000 tons of 2% copper ore, respectively, and are separated by the Keystone group. A 7500-ton mill was being erected to treat this ore, but for the successful working of the whole Inspiration Consolidated this tunnel was necessary. It would be 9 by 11 ft. in cross-section and would be available for public use. The lower court upheld the demurrer of the New Keystone on the ground that the tunnel was for the Inspiration's private use. The Supreme Court at Phoenix on November 27 has confirmed the lower court's decision, arguing that the tunnel as desired as a private way is not one of necessity, therefore the power of condemnation in this instance lies dormant. Curtis H. Lindley of San Francisco and E. W. Rice of Globe appeared for the Inspiration company, and Alderman & Elliott of Globe for the New Keystone company.

Yuma County

The American Girl mine, two miles from Tumco and near Ogilby, has been shut down and 175 men are out of employment. Recent heavy rain flooded the reservoir and then the mine. Unwatering will take two or three months. A good tonnage of low-grade ore exists in the property.

CALIFORNIA

In a *Press Bulletin* of November 28 the California State Mining Bureau states that assessment work on mining claims must be done before the end of the year in the usual manner. The Secretary of the Interior, Franklin K. Lane, in a telegram to the State Mineralogist, F. McN. Hamilton, states that no legislation was enacted which exempts holders of unpatented mining locations from the statutory annual labor. The State Mineralogist is anxious that wide publicity be given the matter, as only a month remains in which to begin work. Many inquiries on this subject have been addressed to the State Mining Bureau, probably because legislation was expected.

Conditions of the oil industry should improve, and it is the aim of the Bureau to aid in bringing about such improvement. The past year has been one of depression, and has seen some valuable oil holdings almost slip from the grasp of American investors. The public must be made to realize the important factors, supply and demand, which underlie the oil business. The state contains immense deposits of oil, and a large demand, but money or credit is needed to join the two. The remaining necessity is the use of brains and co-operation of all interests. For several years ill-informed operators have caused overproduction, and thereby rushed toward financial suicide as well as maiming their more conservative neighbors. It has become a habit to blame the large concerns for all misfortunes and to clamor for more laws or regulations. The prosperity of California rests to no small degree upon the oil industry, which furnishes its only cheap fuel. There are 300 oil-producing companies, 6 marketers, and innumerable consumers. Notwithstanding the importance of oil, there is no adequate means of closely estimating probable fluctuations in supply and price. It is true that there are several monthly summaries voluntarily published by marketers, and if it were not for these the public would have practically no data. However, a business annually involving about $50,000,-

000 and a great many people, deserves more consideration than can be given by a mere summary of conditions.

The State Mining Bureau has recently devised a system of monthly statistics which will be published by the middle of each month. Briefly, it will show the amount of oil purchased, produced, and stored by each of the large companies. The success of this system depends upon the co-operation of the large marketing companies. Most of them have agreed to participate, and it is, of course, inconceivable that any will refuse, because such figures, from an unbiased and official source, will quickly show the advantage and necessity of strong marketing concerns. The fact that they concur in such work will sweep aside accusations that they selfishly manipulate the market. The publication of these figures by the Bureau will be the most effectual barrier to experimental legislation, which aims at big business merely because it is big, and thereby injures every one.

The Kern Trading & Oil Co. brought in a new gusher in the Midway field last week. The well, which is running 'wild,' is estimated to be producing 30,000 bbl. of 26° B. oil per day.

Amador County

Supplementing the October returns of the Plymouth Consolidated as published in the *Press* last week, the following details are from the Company's office in San Francisco. Ore milled, 9000 tons; yield, $44,191; average, $4.91; development cost, 14.9c., working expenditure, $2.322; total cost, $2.588 per ton; and profit, $20,889. This is a concise and interesting way in which to publish monthly returns, and it would be of wide-spread value to mining men of the country if other Mother Lode companies would follow suit. No harm is done in such publicity, while interest in the industry is increased.

Butte County

The Bumble Bee mine, near the old Banner, is being developed by Los Angeles people. The shaft is being sunk, and a cross-cut driven at 400 feet.

Mono County

An examination of placer ground in Mono Lake basin, owned by J. M. Miller, J. A. Conway, C. A. Hilton, and Francis Burke, is to be made next spring by prospective buyers. The area is about 2000 acres, containing 14,000,000 cu. yd. of dredgable ground of good value, and $100,000 is wanted for the property.

Nevada County

A dividend of 6c. per share, amounting to $18,000, has been declared by the Brunswick Consolidated. This totals $89,000 for the current year.——After several months' work, the Delhi vein in the Delhi mine has been recovered, showing 12 to 30 in. of ore at 500 feet.

Placer County

A 5-cu. ft. dredge, 90 ft. long and 40 ft. wide, is being constructed for Lawrence Gardella, of Oroville, near Lincoln. Thirty men are employed and the boat will be finished early in January.

Shasta County

The Noble Electric Steel Co. of Heroult or San Francisco, invites correspondence with owners of deposits of manganese ore, who can supply carload lots, with a view to contracting for the output. Samples for analysis should be sent to the San Francisco office. Additions to the Mammoth Copper Co.'s bag-house are nearly finished. This work has been under way for about five months, and 500 tons of steel has been used. It is said that another 100 miners are to be hired.

The hearing of the case of the Shasta County Farmers' Protective Association against the Mammoth Copper Co. at San Francisco was suddenly suspended on December 1 by Judge Van Fleet, who will visit Redding and the district alleged to be damaged by smelter fume. Two farmer witnesses for the plaintiff, who live 17 and 21 miles from Redding, have been examined.

Sierra County

About 75 tons of machinery and 50,000 ft. of lumber have been delivered to the Red Ledge quartz mine below Alleghany. The mill will be built next spring. A cross-cut has passed through 122 ft. of $4.50 to $7 ore. John B. Moulton is in charge of the property.——A centrifugal pump of 180-gal. per minute capacity has been sent to the Telegraph mine.——A tramway is being erected at the Gold Bluff mine to connect with the mill.

Siskiyou County

Rich quartz is being mined by McDowell & Wood in Le Count's gulch, near Sawyers Bar.——Placer ground on the Salmon river is to be worked by Wilke & Matthews.——This district promises to be active during the winter.

The Rollin Mining Co., of San Francisco, has done a large amount of development at the Black Bear mine. The new 16-stamp mill is working at capacity.

Trinity County

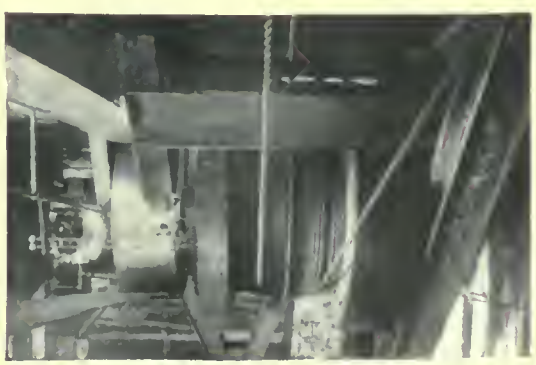
An important instance of 'jumping' has been made public in Weaverville, in which James H. Hoyle of San Francisco filed for record relocation notices on every claim in the Bullychoop group, 10 miles from Douglas City, in the southwestern part of the county. The Bullychoop Mining Co., owned by Georgia people, has spent about $500,000 on its property, including machinery worth $100,000. Five years ago work was suspended owing to internal disputes, and no work has been done since then, according to Hoyle. All the claims have been retained. The Company spent $25,000 on a road to the property, and a large sum on the 20-stamp mill and hydro-electric plant. At one time there were 320 men employed, and 1000 tons of ore crushed per month. The 'jumping' of the whole concern caused surprise in Weaverville, as it is claimed that affidavits of proofs of assessment work on each of the 12 claims have been filed for record regularly each year since the mines were closed. A big lawsuit is probable, but the new owner intends to start open-cut mining in the spring.

Tuolumne County

After negotiating for about two months, a New York company, represented by W. G. Devereux of the Melones mine, and C. H. Segerstrom, manager of the Dutch Gold Mining Co., has bought the well known Dutch mine, and the adjoining property, the Sweeney, at Quartz. The new concern will be known as the Dutch-Sweeney Mining Co. The price paid has not been divulged. The main shaft is down 1800 ft., and is to be sunk deeper. The equipment consists of an electric hoist, compressors, a 40-stamp mill, and other machinery driven by motors. J. L. Brooks will remain as superintendent.

Yuba County

An attempt was made by E. E. Gibbs to rob Yuba No. 11 dredge of its gold on November 29 at midnight. The would-be



LADDER HOIST WINCH ON YUBA NO. 11 DREDGE

bandit formerly worked for the Yuba Consolidated, and was heavily armed for the robbery.

COLORADO

Lake County (Leadville)

The Leadville district is more active than for some time past, owing to new developments, the scheme for unwatering the downtown mines, and the improvement in metal prices. Some doubt has been held regarding the value of orebodies in the area to be drained, but samples of silver and copper ore from a wide shoot in the Coronado, now under water, show what may be found later. The surface equipment at the Penrose shaft, which will be the pump shaft, is rapidly being put into shape.——Lessees in the Little Jonny sent about 1000 lb. of ore to the smelter last week. Metallics weighing 41 oz. was screened out, the remainder assaying 190 oz. gold per ton.—— The New March company is sinking its shaft another 100 ft. ——Various work is under way in the Big Four, Prospect mountain adit, Davis shaft, Gordon, London, Ibex, Tenderfoot, Venture, and Adelaide properties.

Gilpin County

Denver men have secured a lease of the Concrete claims, west of the Gunnell mine on the same vein, and intend to work it extensively.——A vein 17 in. wide and containing high content in gold, silver, and copper has been opened for 14 ft. at 225 ft., in the Bezant mine in Leavenworth gulch. There is 30 in. of low-grade milling ore at the side of the smelting ore.——A cross-cut in the Buckeye, worked by the Gold Cup company, has cut rich gold-silver-lead ore.——About 80 tons of high-grade gold-silver-copper ore has been shipped from the Pittsburg mine in lower Russell gulch. W. Augur is manager.

Ouray County

A 6 by 16-ft. Allis-Chalmers tube-mill has been installed in the Wanakah mill. The 200-ton blast-furnace is to be blown in this week.——Development has been resumed at the Mountain Top mine after two months' suspension.

San Miguel County

Profit of the Tomboy mine in October was $33,000.

Teller County (Cripple Creek)

The new 150-ton mill of the Vindicator is being operated at capacity, and making a good recovery. Five sets of sub-lessees are breaking three grades of ore from ground around No. 2 shaft.——Three to four feet of $60 ore has been opened by a lessee in the Isabella. There are 30 sets of lessees in this property.——The Gold King Mining Co., the closest corporation in the district, paid a dividend of 1c. per share, equal to $10,000, on November 21. This was from accrued royalties on ore shipments.——Two to three inches of sylvanite ore has been opened by M. D. Rapp on the third level of the C. O. D. mine.——Nutter Bros., lessees on No. 2 level of the El Paso, are mining $35 ore from a shoot 2 ft. wide.——Four feet of $25 to $40 ore has been cut on No. 7 level of the Ajax.—— Foundations are being laid at the El Paso for the machinery to take the place of that recently destroyed by fire.

IDAHO

Shoshone County

The Interstate-Callahan mine and mill are being operated three shifts, producing 50% zinc ore.——Eight feet of about 40% zinc ore is now showing in the Silver Cable cross-cut.—— In the Reindeer-Queen there is 12 to 18 in. of 34.2% copper ore, and 5 ft. of high-grade milling ore at 700 ft. depth. The mine is at Stevens peak, and E. B. Crawford is in charge.—— Two fatal accidents occurred in the Bunker Hill & Sullivan mine last week. In one case J. R. Williams was crawling into an ore chute to place some dynamite to release a jamb, when the ore suddenly moved and caught him. In the other instance E. Labus, a motorman on an electric locomotive with a train of ore cars on No. 12 level, was killed by accidentally striking his head against an ore chute.

MICHIGAN

Houghton County

Sand-filling of worked-out stopes in the Copper Range Consolidated mines has been a success. The Quincy company is now trying the system, while others contemplate doing so.—— During October, the Isle Royale mill crushed 44,205 tons of 'rock' in 25 days, yielding 586,120 lb. of copper, not including mass copper.

MONTANA

Lewis and Clark County

Twenty stamps, the first unit of the 60-stamp mill for the Porphyry Dike mine, in the Ten Mile district, near Helena, have started work. This property consists of 330 acres, and contains a large deposit of free-milling gold ore. The plant is operated by electric power. George Gordon is manager for the James Breen interests.

The old Drumlummon mine at Marysville, which has produced a great quantity of gold and silver, was sold on November 27 for $11,486, the result of a suit against the owners for $10,000 and court costs. The new owners are B. Betor, F. Trudell, and C. S. Caird.

Lincoln County

Superintendent John Johnson of the Lukens-Hazel mine was in Libby last week, and stated that the day and night shifts are opening two veins of rich ore in two adits. Twelve inches of smelting ore has been cut in No. 1 adit. Arrangements are under way to erect a concentrating plant next spring.

Silverbow County

On November 21, 'Muckle' McDonald and Joseph Bradley of the Butte Mine Workers' Union, were sentenced to three and five years' hard labor, respectively, for complicity in kidnapping Patrick Towey. McDonald became leader of this union after the split with the Western Federation of Miners, but Bradley was considered the 'brains' of the new concern. Joseph Shannon of the executive committee, was declared not guilty by the court at Butte.

NEVADA

Churchill County

The Nevada Hills company reports as follows for October: ore treated, 6213 tons; average per ton, $7.136; net profit, $6590; and resources, $253,352. The last named item includes silver worth $14,077 (28,000 oz.); concentrate and bullion in transit, $17,818; and value of mill solutions, $20,000.

Esmeralda County

Eighteen feet of ore has been cut in rise 503-C above the 1017-ft. level of the Velvet claim of the Jumbo Extension. This is the downward extension of the shoot which has given rich rock at 9.52 ft. The ore contains gold, silver, and copper.

Humboldt County

Rochester is showing considerable activity at present in its mine development, new mill, and railroad. The 1300-ft. level of the Seven Troughs Coalition is opening well, and a winze below this point is down 25 ft. in good ore.

Lander County

It is proposed to ship from 20 to 40 tons of ore per day from McCoy, the gold-silver area found on May 23, 1914. This place is 29 miles south of Battle Mountain. The principal rocks are rhyolite, porphyry, and dolomite, according to Guy E. Pierson of Salt Lake City.

Nye County

(Special Correspondence.)—The shaft of the Jim Butler company has just been retimbered to the depth of 700 ft., and during this work a new double-drum Nordberg hoist was installed, which is operated by a 125-hp. variable speed motor.

This hoist is capable of handling a gross load of 3900 lb. and is geared to give a speed of 700 ft. per minute. Of this load, 2600 lb. is counterbalanced by the use of the Balliet system, which makes a variable weight at all points of the cage's trip through the shaft, compensating for the weight of the cable, cage, and car, and making a large saving in power that would have been required otherwise.

A vein of rich ore, 8 or 10 in. wide, has been cut in the Mizpah Extension, and haa caused considerable comment in the stock markets. The vein is running eastward through the trachyte formation. At this time the quantity of ore has not been determined, but thus far it is not great. Ore is now being sacked for shipment.

Tonopah, November 27.

A good tonnage of $5 to $15 gold ore has been developed by John Mullen and Salt Lake City people in the Altmore mine, near Springdale. It is only 1500 ft. from the Pioneer mine, which is milling ore. An electric hoist is to be added to the equipment.

A 5 by 20-ft. Allis-Chalmers tube-mill weighing 14 tons is being hauled from Tonopah to the Mushett and Wittenberg plants at Manhattan by a team of 18 horses. Ten other horses will be added to the 18 when climbing hills. Pebbles for the tube-mill will be supplied by Maria' chalcedony quarry, eight miles northeast of Manhattan. These are doing good work in Tonopah mills.——Satisfactory results are being made in crushing oxide ore from the White Caps mine.——Construction of the transmission line from Manhattan to the old Belmont district is almost finished. The deepest shaft, 500 ft., in the area is to be unwatered at once.

Six mines at Tonopah last week produced 9687 tons of ore valued at $190,326.———The Extension company'a profit was $49,442 in October.——At the annual meeting of the Midway at Phoenix, Arizona, on January 4, it is proposed to reorganize the Company.——The Belmont will pay 12½c. per share on January 1.——The limit of windlass work having been reached at Tonopah, there is a lull in prospecting, although considerable work is under way. Power hoists will soon be installed.

Storey County

During the past week 200 tons of $14.02 ore was extracted from a two-compartment rise at 2500 ft. in the Con. Virginia. There were 350 tons sent to the Kinkead mill.——At 2300 ft. in the Mexican, 22 tons of $16.40 ore was mined.——The Yellow Jacket mill received 579 tons from the Belcher mine, and 471 tons from other mines.——Gypsum insulation is being put on pipes and pumps at the Reidler station of the C. & C. pumping station.

TENNESSEE

Polk County

On December 1 the Tennessee Copper Co. paid off $200,000 of the 6% gold bonds issued for construction of the sulphuric acid plant, leaving $800,000 outstanding. Acid production is the largest in the Company's history.

UTAH

Beaver County

Electric power from the Beaver River Power Co. is to be used for the plant at the Moscow mine. This power concern has 2000 hp. available, and is extending its field of operations, having 150 miles of line to mining districts.——The Beaver Gold Mining Co.'s shaft has cut ore at 60 ft., which is supposed to be a continuation of the Sheep Rock vein, opened one mile distant.

Juab County

Shaft repair work is finished at the Chief Consolidated at Tintic, and 50 men have started on development.——Twenty-six men are working on leases down to 700 ft. in the Eureka Hill.——Some 6 to 8% copper ore is being mined in the Dragon.——Promising developments are taking place in the Scranton and Tintic Zinc properties.——Ore shipments from the Tintic district last week totaled 69 cars, about 2200 tons, from 9 mines.

Salt Lake County

Lessees have opened two shoots of copper-lead-gold-iron ore in the Montana-Bingham adit, being driven through Bingham Amalgamated ground. The adit is in 3500 ft., and the Congar vein is in 750 ft. farther.——The Miller Investment & Leasing Co. of Salt Lake City, has secured control of the Peruvian Consolidated Mining Co.'s claims in the Alta district for $125,000. Several adits were driven by J. P. Clays, former owner, and the new concern will extend one adit to open an orebody. Plans are under way to construct an aerial tramway 3700 ft. long. A compressor, drills, and a mill will probably be installed next spring. Albert Burndies is manager.——In white limestone formation, in a distance of 863 ft. the Alta Tunnel & Transportation Co. has cut stringers of ore assaying 17% copper, 21 oz. silver, and $1.60 per ton gold.

Summit County

Vigorous development work is proposed for the Thompson-Quincy mine at Park City, which was recently examined by F. Sommer Schmidt. Revenue of the Company during the past

MAP OF UTAH.

financial year was $9937 from ore sales and $4616 from sales of shares. The balance on hand is $244, and the indebtedness on October 31 was $44,382.——Ore from the Revelator mine in the Snake Creek district has been settled for at 81.8 oz. silver, 41.4% lead, and 1% copper. Samuel Hair is superintendent.

WASHINGTON

A new map of this state, containing the latest information, on a scale of 8 miles to 1 in., and 32 by 48 in., has been issued by the U. S. Geological Survey, and is sold at Washington, D. C., for 25 cents. The state geologist, Henry Landes, co-operated with the chief geographer, R. B. Marshall.

Chelan County

One ton of high-grade molybdenite, worth $2000, was shipped through Wenatchee last week from the Aurelia Crown mine, at the head of Chelan lake. Robert Dahl is in charge of the property.

FERRY COUNTY

(Special Correspondence.)—The Western Union Mines Co., at Republic, is employing 105 men. At the Surprise mine this Company has installed a 90-hp. Diesel engine, and is also erecting a small compressor to help the other one and supply air for eight drills. The mine is being unwatered to the 700-ft. level, where an ore-shoot 400 ft. long has been opened, with high-grade ore below this point. The Insurgent claim has been leased to the Company, and it will be worked with the Lone Pine and Last Chance claims. The latter is being reopened at 500 ft., and when unwatered the 540-ft. level will be worked, where rich ore is said to be showing. From the 500-ft. level, 150 tons of $50 ore has been shipped to the smelter, and there is estimated to be 2500 to 3000 tons opened. The Company is sending 80 tons of $10 ore per day to the San Poil mill, in which a new set of steel rolls is being installed. The Company will take over the plant built by the New Republic company and add another tube-mill and Oliver filter, to bring the capacity up to 200 tons per day. It is planned to have two 500-hp. Diesel engines in a central power plant, increase the mill's capacity to 1000 tons per day, and supply the town of Republic and all the mines and mills with light and power. F. M. Croft, of West Virginia, is president of the Western Union Mines.

Republic, November 20.

The Western Union Mines Co., of Republic, is calling for bids for plant to generate 1000 hp., the machinery to consist of two 500-hp. Diesel engines, generators, and other electrical appliances.——The Alliance Mining Co., of Republic, has acquired the mines and plant of the Anaconda Gold Mining & Reduction Co. for $171,000. Of this, $120,000 was paid in Alliance shares, and the remainder is an indebtedness by the purchasers. C. M. Hansen, of Spokane, is president.

PEND OREILLE COUNTY

Since the railway has been opened in the Okanogan valley, the old Ruby district is regaining activity. In the early nineties there were 1500 people there. Two cars of $75 silver ore have been sent from the Arlington mine to the Tacoma smelter. It is estimated that there is 16,500 tons of ore ready for stoping. A caterpillar tractor will probably be used to haul ore to Okanogan.

SPOKANE COUNTY

It was proposed to reopen the Spokane Stock Exchange on November 30, according to the secretary, C. E. Mallette.

STEVENS COUNTY

The United Copper Co., of Chewelah, according to Conrad Wolfe, of Spokane, is to add a tube-mill to its plant, and is testing several flotation processes.——New mining machinery has been delivered to the Hecla mine for its further development.

WYOMING

A new map of this state, a single sheet 40 by 50 in., printed in black, has been issued by the U. S. Geological Survey. It contains the latest county boundaries, railroads, streams, etc., on a scale of about 1 in. to 16 miles, and is sold at Washington, D. C., for 30 cents. The state's area is 97,914 square miles.

CANADA

ALBERTA

(Special Correspondence.)—The Edmonton Industrial Association Drilling Co. has been drilling a well at Viking (about 75 miles east on the Grand Trunk Pacific) under an arrangement with the city that, if it found gas in certain quantities and pressure, the city would take it over and reimburse the Association. At 2340 ft., at 3 a.m. on November 4, the well came in strong and blew wide open until about 4 p.m. November 7. I got there about 5 p.m. that day (on a special train run for the purpose of taking a crowd down) and the gage stood at 450 lb. The Company had run a pipe out about 100 ft. and let the gas burn there. After it had been burning some time, I watched the gage and it stood at 300 lb. The International Drilling Co. had the contract for the drilling, and officials measured the volume as 9,350,000 cu. ft. and gave out the statement that it is next to the big well at Bow Island field from which Calgary gets its supply. This gas has a distinct odor, and I would not be surprised to see that territory bring in oil at a little greater depth. It is the most important find in the province this year, in my opinion. They had gas at 2193 ft. and it kept getting stronger until they ran into the strata at 2340 ft., when the big volume came in. From an examination of the samples kept from the log, I judge it is in either the lower Benton or the upper Dakota that the discovery was made, more likely the Dakota. It is possible, owing to unconformity, that the gas comes from the Devonian, and this opens distinct possibilities of profitable oil as well as gas.

Edmonton, November 20.

BRITISH COLUMBIA

It has been officially stated that two of the eight blast-furnaces of the Granby plant at Grand Forks are to be blown in as soon as possible. A reduction of 25% of the wages at the time of the shut-down, early in August, will become effective.——The Josie mine of the Le Roi No. 2 company was reopened on November 23 with 40 men.——Good reports come from development work of the British Columbia Copper Co. since August. From March 1 to November 1 drilling totaled 20,500 ft., and 15,000 ft. of trenching done. One orebody is 600 ft. long and 100 ft. wide, and another 500 ft. long with a width varying from 50 to 150 ft. About 145,000 of the 591,709 outstanding shares of the Company have not been exchanged for the stock of the Canada Copper Corporation. This exchange involved a $1 subscription to the debenture bonds of the Canada Corporation for each share of British Columbia stock held.

ONTARIO

The emptying of Kerr lake has been suspended for the winter. Owing to the depth of mud in the bottom, work was interfered with considerably.——After being hung up for 105 days, 20 out of 40 stamps of the Temiskaming mill started again on November 16. During the past six weeks, about 5000 tons of ore was broken in the mine stopes. The new vein at 750 ft. is being underhand stoped.——Recent prospecting at La Rose Extension has uncovered for 50 ft. a narrow vein assaying 2500 to 3000 oz. per ton. It will also be developed underground.——At Porcupine the Pet shaft is to be sunk to 200 ft. The mill is treating 15 tons per day.——Stopes at 100 and 200 ft. are supplying the Vipond mill. The new refinery is ready for operation.

YUKON

What the *Dawson Weekly News* calls a 'smashing run' was made during the week ended October 27 by No. 3 dredge of the Canadian Klondyke company, operating close to Dawson. The gravel was 30 to 35 ft. deep, with 7 ft. exposed, the ground and gravel thawed, with a soft bedrock. According to the general manager, J. W. Boyle, the record is as follows:

Operating time, hours (possible 168)	163.83
Gravel handled, cubic yards	110,045
Average per hour, cubic yards	674
Average depth cut, feet	30.6
Average width cut, feet	280
Power used, kilowatt-hours	106,000
Power used per yard, kilowatt-hours	0.96

A new bucket-line was recently put on this boat, the buckets having an extra 2 in. on the lips, making 17 cu. ft. capacity instead of 16 cu. ft. The dredge crew comprises Arthur Gibson, dredgemaster; Stanley Gibson, Joe McKinnon, and George Munroe, winchmen; J. C. Campbell, Sam McLellan, and James Forbes, oilers.

PERSONAL

B. L. Eastman is home from British Columbia.

G. W. W. Mackinnon is interned in Austria as a prisoner of war.

Frank E. Wilson has returned to New York from South America.

Cecil Cropper has returned to London from the Federated Malay States.

John G. Kirchen of the Tonopah Extension, Nevada, is in San Francisco.

Karl E. Lloyd, recently of the Central Chile Copper Co., has returned to the United States.

Kejiro Nishio, mining engineer from Tokyo, Japan, is visiting the mines and mills of the copper country, Michigan.

G. L. Sheldon expects to go to Eureka county, Nevada, on professional examination during the first part of December.

Denis M. Riordan is on his way to California to inspect the mining properties owned by the General Electric Company.

A. C. Lawson has been made acting dean of the College of Mines of the University of California, succeeding S. B. Christy.

Frederick Bradshaw and W. H. Blackburn of Tonopah have been at Reno attending a meeting of the Nevada Mine Owners' Association.

D. C. Jackling has returned to Salt Lake City from a visit to the Ray Consolidated property in Arizona, and the Chino property in New Mexico.

T. M. T. Rasborg has retired from the board of the First National Copper Co., following the death of his brother, and their places have been filled by E. M. Buchanan and J. A. Young.

J. K. Turner, general superintendent for the Jumbo Extension Mining Co., has been appointed by Governor Taskie L. Oddie as a Nevada delegate to the American Mining Congress at Phoenix, Arizona, December 7 to 11.

A. L. Queneau writes to a friend in New York that since August 5 he has been at the front with his artillery regiment. Those of his friends who wish to write him can address him in care of Miss Blaisdell, 5 Rue Napoleon, Paris.

George Kingdon has been appointed general superintendent for the Cananea Consolidated Copper Co. He hopes to start development work before the end of the present year. He recently visited the United Verde Extension property with S. P. Applewhite.

Robert Hallowell Richards will be given a complimentary dinner, on December 7, in recognition of his fifty years as a devoted 'Tech' man by the corporation, faculty, and alumni of the Massachusetts Institute of Technology, at the Copley Plaza Hotel, Boston.

William Hague, director of the North Star Mines Co.; George W. Starr, managing director of the Empire Mines, and C. A. Brockington, superintendent of the Golden Center, have been named by W. G. Thomas, president of the Chamber of Commerce, to represent Grass Valley at the American Mining Congress at Phoenix.

Nominations for officers of the Geological Society of America are: Arthur P. Coleman, Toronto, Canada, president; L. V. Pirsson, New Haven, Connecticut, first vice-president; H. P. Cushing, Cleveland, Ohio, second vice-president; Edward O. Ulrich, Washington, D. C., third vice-president; Edmund Otis Hovey, New York City, secretary; William Bullock Clark, Baltimore, Maryland, treasurer; Joseph Stanley-Brown, New York City, editor; Frank R. Van Horn, Cleveland, Ohio, librarian; and Charles K. Leith, Madison, Wisconsin, and Thomas L. Watson, Charlottesville, Virginia, councilors.

SCHOOLS AND SOCIETIES

The Cobalt branch of the Canadian Mining Institute met on November 25. The principal discussion was on C. G. Campbell's paper, 'The Sampling and Assaying of Cobalt Ores,' presented at the Institute's meeting at Montreal last March.

The Cleveland Engineering Society, Ohio, met on December 1, when Thomas D. West read a paper entitled, 'The Foundry as an Adjunct to Engineering.' On December 8, J. V. Emmons will discuss 'The Structure of Tool Steel.' Both of these papers are illustrated.

Night schools for mining instruction were started at Miami, Oklahoma, some time ago, in charge of Mead S. Johnson, and have been a success. Assaying and chemical apparatus is available for students, also for mechanical drawing. The new schoolrooms were opened on November 23.

The American Mining Congress has issued a 58-page illustrated pamphlet covering its past work, the meeting at Phoenix, Arizona, on December 7-11, the U. S. Bureau of Mines and Geological Survey, and articles on Arizona and districts. A provisional program of the meeting is given on p. 869.

The Michigan College of Mines' *Alumnus* for October contains, among other matter, a paper on 'Drying Iron Ore on the Mesabi Range,' by Edwin J. Collins; 'The Rainbow Lode Shaft,' by E. C. Reeder (a reprint from the *Mining and Scientific Press*); and 'Data on Iron Mining,' by E. S. Dickinson.

The School of Mines at Socorro, New Mexico, has 52 students, and according to Fayette A. Jones, president of the department of education, the income last year was $27,510, of which $24,392 was from the state. The total value of the buildings, equipment, and 20 acres of ground is $102,633. It costs about $500 per year to teach each student.

The University of California expects several hundred new students at the start of the second half-year on January 11, 1915. The attendance at present is 8181 students. According to Henry T. Claus in the *Boston Transcript*, the numbers at various universities of the United States are as follows:

1. Columbia	10,961	12. Syracuse	4,000
2. California	8,181	13. Nebraska	3,793
3. Pennsylvania	7,368	14. Yale	3,289
4. Michigan	6,302	15. Washington	2,738
5. New York	5,875	16. Iowa	2,725
6. Illinois	5,620	17. Pennsylvania	2,246
7. Ohio	5,395	18. Purdue	1,961
8. Wisconsin	4,901	19. Stanford	1,884
9. Cornell	4,848	20. Massachusetts Institute of Technology	1,818
10. Northwestern	4,632	21. Princeton	1,665
11. Harvard	4,516		

Forty members of the Columbia branch of the American Institute of Mining Engineers were present at the fourth annual meeting at Spokane on November 20. The secretary-treasurer, L. K. Armstrong, reported that membership had increased from 120 to 150, and that the financial condition was good. F. A. Ross, of Spokane, was elected president, and Rush J. White, of Wallace, Idaho, vice-president. The principal address was made by F. M. Handy, of Pullman, associate professor of geology at the university, on the 'Economic Geology of Eastern Washington.' Other speakers were Loren A. Campbell, of Rossland, B. C., of the West Kootenay Power & Light Co.; Oscar Lachmund and Frederic Keffer, Greenwood, B. C., of the British Columbia Copper Co.; G. H. Wyman, Jr., Wallace, Idaho, flotation and concentration engineer for the Federal and Hercules mining companies; Sam H. Richardson, of Republic, and D. C. Livingston, Moscow, of the mining department at the University of Idaho.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, December 3.

Antimony	15 —15¾
Electrolytic copper	13 —13¼
Pig lead	4.05— 5.00
Quicksilver (flask)	$55
Spelter	6½— 6¾
Tin	34½—36
Zinc dust, 100-kg. zinc-lined cases	10

EASTERN METAL MARKET.

(By wire from New York.)

NEW YORK, December 3.—Generally the market is better. Copper is strong and advancing, lead quiet, and spelter firm. The following dividends have been declared: Calumet & Arizona, 50c.; Goldfield Consolidated, 15c., or $533,872, on February 27; Quincy, 50c.; and Yukon Gold, regular quarterly of 7½c. per share on December 31.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	63.01	57.58	July	58.70	54.90
Feb.	61.25	57.53	Aug.	59.32	54.35
Mch.	57.87	58.01	Sept.	60.53	....
Apr.	59.26	58.52	Oct.	60.88	....
May	60.21	58.21	Nov.	58.76	....
June	59.03	56.43	Dec.	57.73	....

The trend of prices has been upward this week, as follows: New York, 48.50, 49.25, 49.12, 49.50, 49.75, and 49.87c.; and London, 23.00, 22.81, 22.75, 22.78, 23.00, and 23.06d. per ounce. In November the highest was 49.87c., and lowest 47.62c. in New York. Producing companies are still storing metal, selling as they find necessary. It is said that the Tonopah Belmont has 1,250,000 oz. unsold. Fair support is coming from India, and a considerable shipment left London in the week ended November 19. Stocks in London are about 20,000,000 ounces.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Nov. 26	Holiday	Oct. 21	3.50
" 27	3.80	" 28	3.50
" 28	3.80	Nov. 4	3.50

The figures, in tons, for three important companies are as follows:

	October.	September.	July.
Chino	3,060,000	3,237,869	5,087,750
Ray	3,278,348	3,180,000	6,008,061
Utah	6,765,396	6,672,194	13,768,958

The export situation is discussed in the New York letter of this issue.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slighly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Nov. 5	55.00	Nov. 19	55.00
" 12	55.00	" 25	55.00
		Dec. 3	55.00

Monthly averages.

	1913.	1914		1913.	1914
Jan.	39.37	39.25	July	41.00	37.50
Feb.	41.00	39.00	Aug.	40.50	80.00

English purchases have been heavy, and with the continued shut-down of the Butte & Superior, there has been a marked advance in prices. Ore at Joplin has risen to $42 to $45 per ton, basis of 60% metal.

CYANIDE

Mills using cyanide in the Philippine Islands are reported by the Bureau of Science to have been sufficiently supplied in October, but uneasy as to the future. In a special press bulletin the Bureau quotes from the 'Press.' The 'Sun,' carrying a cargo of cyanide from Rotterdam, has been delayed by rough weather on the Atlantic, but put into Boston, November 28.

New York Metal Review

The outlook in business generally is brighter. The effects of war buying are beginning to spread out to lines not benefited at first. Pig iron has been sold heavily, but at ridiculously low prices. The steel trade needs the stimulus which can only be given by more liberal railroad buying, and this will come only when the Interstate Commerce Commission renders a decision in the railroad freight rate case. Many machine tool builders have done splendidly in selling for export, and in selling tools to enable the fulfillment of contracts for war material. The Bethlehem Steel Co. has bought heavily of machine tools, likewise of motors to run them, and the motor company has in turn bought several machine tools. This Company and E. W. Bliss are making shrapnel, and the motor company has bought a great deal of machinery. So has the Fore River Shipbuilding Co. High-grade steel for shrapnel is being purchased. Hydraulic presses for making smokeless powder have been ordered. Steel has been bought for horseshoes. Makers of binoculars cannot fill the orders proffered to them. Gun and ordnance manufacturers have work ahead for many months. Many other articles are required which indirectly result in greater consumption of metals. In a way, this war business is unhealthy, but it will help tide things over.

All of the metals took on a better tone in November, and prices advanced without exception. In copper there was heavy buying, most of it being on domestic account, and the movement left the market on a much more substantial basis than it had been, despite the continuance of interference with exports. Lead was subjected to three advances, and a good buying movement was concluded for the time being. On the whole, spelter advanced as a result of support from abroad. Tin varied considerably as usual, through fears that there would be a shortage in the month's supply; but the destruction of the German man-o'-war *Emden*, and the arrival of 830 tons on one ship, allayed apprehension. Antimony maintained a high level throughout the month. Aluminum advanced about 1c., but was uninteresting. The New York Metal Exchange resumed trading in tin, lead, and spelter on November 9.

COPPER

Actual need on the part of consumers, and the low price of 11.25c. cash, New York, which prevailed in the first 10 days of November, brought about the heaviest buying movement of many months. The demand did not cease until about November 20; meanwhile quotations advanced steadily until, on November 23, 12.50c. cash was reached. Buying was almost entirely on domestic account, exports being seriously hampered by the refusal of Italian steamship lines to take copper as a part of their cargoes. Metal which was aboard the steamer *Kroonland* was confiscated at Gibraltar, and the consignors were notified by the English authorities that a prize court would determine its disposition. The action of Great Britain caused a second protest to be sent to Washington by the producers who made the shipment. The Italian government added to the complexities of the situation by prohibiting the export of copper from Italy, though it announced that it would not interfere with its transit through that country. If a guarantee were given that the metal was to be used in Italy or Switzerland, there would be no interference, though copper shipped subject to order would be under suspicion. The advances referred to began almost simultaneously with the buying, prices going up about ¼c. each day from November 11 on. In the movement, several million pounds was taken, one large consumer alone taking over 5,000,000 lb. There also was good buying on the part of a large London metal house, whose representative was in New York. Makers of hot rolled sheet copper advanced their price, on November 19, ½c. to 17c., and on November 23 made a further advance to 17½c. Brass products were advanced also. The general belief of the trade is that the end of the movement left the market on a healthy and sound basis, though a few hold that the advance was too rapid and that the deadlock which will ensue must terminate in lower prices before another movement can be begun. Lake shared in the activity, it being reported that some producers' stocks had been practically exhausted. The quotations for Lake advanced from 11.50c. cash, at the first of the month, to 12.62½c. on November 23. Export figures for November are unavailable at this writing, but those from the United States in 10 months of this year, as compiled by C. Mayer, secretary of the New York Metal Exchange, total 312,964 tons, against 322,399 tons in the same months of 1913. The Waterbury average for October was 12.25c. per pound.

LEAD

Quotations advanced three times in November. From the first of the month until November 12 the New York price stood at 3.50c., when it went to 3.60c. On November 17 there was another advance to 3.70c., and on the 19th it went to 3.90c. Even at the price last named the metal is cheap. Heavy buying which began in October lasted into November, and thousands of tons were taken by both domestic and foreign buyers, and the activity left both producers and consumers in a comfortable position. Advices from England and Russia state the demand in those countries to be excellent, principally because of the war. The large interests led the way in the month's business.

SPELTER

The quotations for spelter dipped a little from 5.05c. New York in the first few days of November, then gathered strength and advanced steadily until 5.30c. was touched on November 24. October exports are estimated at 6175 tons, of which 4454 tons went to England. The good foreign demand was largely responsible for the advances. Domestic requirements were not heavy, but this did not impair the strength of the market.

TIN

The principal feature of the month consisted of recurring fears that there would be a shortage of tin, which caused prices to fluctuate in the manner so characteristic of the metal. On November 2 the quotation was 31.80c., at which figure a good business was done, the activity continuing until November 6. On the 4th the quotation was 33.25c.; 10th, 34.25c.; 17th, 32.50c.; 18th, 32c.; 24th, 33.87½c.; and 27th, 33.50c. was bid. Great relief was afforded to the market when the news came early in the month that the German cruiser *Emden* had been destroyed. With this menace to shipping removed from the Indian Ocean, it was felt that shipments from the Straits would come more freely. In the latter part of the month a good business was done, particularly in futures. A shortage was anticipated near the close of November, but fears were dissipated by the arrival of the steamer *Marquette* with 830 tons. The deliveries for consumption in October were good, amounting to 3700 tons. In that month arrivals at Atlantic ports totaled 2043 tons, and those at Pacific ports, destined for the East, 1200 tons. All deliveries in 10 months of this year totaled 36,147 tons, a decrease of 800 tons as compared with the same time in 1913. The total visible supply October 31 was 10,894 tons, against 14,452 on September 30. Arrivals to November 27 totaled 2410 tons, and there was afloat on that day 1800 tons.

ANTIMONY

Quotations early in the month were 16c. for Cookson's, 15c. for Hallett's, and 13.50c. for Chinese, but they soon advanced to 17 to 18c., 15 to 16c., and 13½ to 14½c., respectively, and these levels held throughout the month despite the fact that there was no great demand at any time. The price was maintained by continued reports of foreign requirements and the belief that domestic consumers' stocks were well nigh exhausted. The needs of war were also expected to revive demand.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.

Litharge, com'l, per 100 lb.	8.00	9.50
Manganese ox., blk., dom. in bags, per ton	20.00	25.00
Manganese ox., blk., Caucasian, in casks, per ton (85% MnO_2—8% Fe)	65.00	120.00
Nitre, double ref'd., small cryst., bbl., per 100 lb.	9.00	11.00
Nitre, double ref'd., granular, bbl., per 100 lb.	8.50	10.50
Nitre, double ref'd., powdered, bbl., per 100 lb.	9.25	11.25
Potassium bicarbonate, cryst., per 100 lb.	14.00	16.00
Potassium carbonate, calcined, per 100 lb.	18.00	30.00
Potassium permanganate, drum, per lb.	0.20	0.30
Silica, powdered, bags, per lb.	0.03	0.05
	Min.	Max.
Soda, carbonate (ash), bbl., per 100 lb.	1.45	1.75
Soda, bicarbonate, bbl., per 100 lb.	2.00	2.50
Soda, caustic, ground, 98%, bbl., per 100 lb.	2.75	3.25
Soda, caustic, solid, 98%, drums, per 100 lb.	2.50	2.75
Zinc shavings, 850 fine, bbl., per 100 lb.	12.00	14.00
Zinc sheet, No. 9—18 by 84, drum, per 100 lb.	No quotes	

*Extra charge for packing nitric acid for shipment to conform to regulations.

Roessler & Hasslacher quoted as follows on November 16:

Ammonia, anhydrous, in 50-lb. cylinders, per lb.	$0.27
Arsenic, white powder, in 500-lb. bbl., per lb.	0.06
Cobalt oxide, black, in 10-lb. tins, per lb.	1.05
Cyanide, potassium, 38-4% cyanogen, per lb.	0.25
Cyanide, sodium, 51% cyanogen, per lb.	0.25
Sodium, metallic, in 1-lb. tins, per lb.	0.40

Foreign shipments of potash are being received regularly.

COMPANY REPORTS

NEVADA WONDER MINING COMPANY

The eighth annual report, year ended September 30, of this Company at Wonder, Nevada, in charge of J. A. Burgess, contains the following information: Mine development totaled 4126 ft. The Nevada Wonder shaft was sunk three compartments wide from 1033 to 1342 ft.; and the Hidden Treasure and Wonder Extension were sunk two compartments from 182 to 308 ft., and 300 to 611 ft., respectively. The deepest workings are at 1300 ft., and the horizontal extent is 3400 ft. from end to end. Work in the claims acquired from the Hidden Treasure and Wonder Extension companies has given good results. A new orebody, called the Extension ore-shoot, was opened in Last Chance No. 1 claim. At 500 ft. depth it is 260 ft. long. At 300 ft. there is 40 ft. of ore, and a drift from a cross-cut from the Extension shaft at 800 ft. showed 35 ft. of ore assaying $20 per ton over 3 ft. The 1000-ft. drift

WONDER MINE AND MILL, LOOKING WEST.

from the Nevada Wonder shaft is yielding milling ore from the shoot, which has been opened at 300, 500, 800, and 1000 ft. A winze is to be sunk from 1300 to 1600 ft. to prove three orebodies. Mining cost $2.85 per ton of ore broken. Total cost of mining operations was $4.65 per ton, compared with $3.32 in the previous year. This is due to increased development and tramming broken rock, etc. A new 125-hp. hoist motor, with automatic magnetic control, increased the speed of hoisting from 400 to 500 ft. per minute. Two sets of Draeger rescue apparatus were purchased for the mine.

The mill superintendent, E. E. Carpenter, reported that the stamps worked 92.1% of the possible time, crushing 48,570 tons of ore, equal to 133.1 tons per day, or 13.31 tons per stamp-day. The cyanide plant made a recovery of 95.1% gold and 92.4% silver, the metals extracted being 10,905 oz. gold and 874,085 oz. silver, worth a total of $702,644. The direct cost was $2.743, and indirect, 68.2c., a total of $3.425 per ton. Another filter was added to the two in operation. Talcy ore hindered good work in January, February, and April.

The Company had a total net income of $247,783, which, added to the previous surplus, made $839,035 available. Two 10% dividends absorbed $281,636, leaving a surplus of $557,369 on September 30, 1914. Assets included silver worth $54,956, or about 110,000 oz., and cash $55,231.

The Simmer & Jack Proprietary, Transvaal, produced $3,840,000 from 769,600 tons in the year ended June 30, 1914. The cost was $2.96 per ton; operating profit, $1,540,000; and dividends, $1,630,000.

New Machines and Devices

The 'Iron Finlander'

A new ore-loading device which is being offered to the public by the Lake Shore Engineering Works, has been nicknamed the 'Iron Finlander.' The loader is designed for use in iron, copper, and coal mines in drifts 8 by 8 ft. and possibly smaller. It has an extreme height from the top of the rail to the top of the machine of 5 ft., an extreme width of 3 ft. 9 in., and an extreme length of 14 ft., including the shovel; or with the shovel removed, 11 ft. It can be made to operate on any gage of track and is self-propelling, and has a total weight of 6500 lb. The conveyor-belt, which is of rubber, is 22 in. wide and is the only part of the machine which is not made of steel. The machine has a capacity of 40 tons of material per hour, and is designed to be operated by either air or electricity. It is expected that the air drive will be popular, as the exhaust from the machine will aid materially in the ventilation of the drift in which it is placed. The loader has six different motions, all of which are controlled by the operator. It propels itself forward and backward, operates the conveyor and shovel in a vertical arc of 30 degrees and in a radial arc of 60 degrees, and at the same time drives the conveyor-belt and operates the driving mechanism for the shovel. With such a combination of motions, as with the steam-shovel, a great deal will depend upon the ability of the operator to get the best output from the machine.

The ore loader is made of three distinct parts which may be disconnected with very little difficulty in order to move the machine from the surface to points underground or from one level to another. The truck constitutes one portion, the frame with driving mechanism the second, and the conveyor-belt and shovel the third. All of the chains for driving the machine are heavy automobile chains. The drive gear from the engine to the main shaft is of the Wnest patented herring-bone type. The machine is completely enclosed, compact, and securely covered so that dirt cannot interfere with its operation. The Lake Shore company's engineers have been working on the machine for the past five years. The patentees are V. C. Holby, N. P. Flodin, of the Company, and M. E. Richards, manager for the Judson Mining Co., and Joseph Hodgson, general superintendent for the Copper Queen Consolidated Co., Bisbee, Arizona. The Company intends to build three sizes of the machines which will be suited to the various conditions met in the conduct of ordinary mining operations. The demonstration machine is at present in operation at the Judson mine at Alpha on the Menominee range.

The accompanying electro is that of a postal card which is being used by the Dixon company to introduce a product which this Company is offering to the trade known as 'Dixon's Boiler Graphite.' Good engineering practice urges the use of graphite in many boilers, and the grade best adapted to this purpose has been the subject of considerable investigation by this Company. The purpose of boiler graphite is to reduce the fuel consumption, prevent the hardening of scale, give to the surface of the boilers a smooth polish, prevent pitting, and make the removal of scale easy by a gentle mechanical action. The Dixon company has a booklet for distribution entitled 'Graphite for the Boiler,' which will be sent upon application to the graphite department of the Joseph Dixon Crucible Co., Jersey City, New Jersey.

Commercial Paragraphs

The Continental Fibre Co., Newark, Del., has published a booklet entitled 'Insulation.' In this publication are enumerated some of the striking peculiarities of this Company's products and a few of their varied uses. The principal products of the Company are 'Vulcanized Fibre,' 'Bakelite-Dilecto,' and 'Continental Bakelite.'

The Denver Quartz Mill and Crusher Co., Denver, Colo., has recently supplied the following equipment for the Kuykendall property in the Tarryall district of Park county, Colorado: one automatic Denver ore feeder; one 8 by 12-in. Denver crusher; one No. 2 Denver quartz mill; two 54 by 96-in. amalgamation plates; two No. 5 Wilfley tables; and one Monell slimer.

The Connersville Blower Co., Connersville, Ind., has recently added Catalogue No. 16 to the Company's literature. The present catalogue is most attractively published and devoted to the cycloidal pumps manufactured by this Company. The pumps are manufactured in quite a number of styles and for a great variety of uses. The rotary pump is not new, but its applications are perhaps not fully realized by the users of pumps generally. Among the uses for which this type of pump has been designed may be mentioned condenser service, circulating service, handling large volumes of water against low and medium heads, handling magmas and pulps, as fire pumps, also for cyanide plants and vacuum production in all stages. In construction these pumps are simple, compact, and powerful; they have no valves, springs, or small parts to get out of order or need renewing. Neither are foot or discharge valves necessary, and there are no internal parts requiring lubrication. There are no reciprocating parts and hence no reversals to limit the speed. They may be driven by belt, direct connected with an engine or water wheel, or by motor through gear and pinion. The pumps are built with displacements which vary from 1/20 gal. per revolution to as large as 70,000 gal. per minute. The catalogue is fully illustrated and contains a large amount of information on the subject of this type of pump. The discharge from the pump is continuous but not uniform, and in order to provide for the variation in flow, it is the practice to equip the pumps with ample air chambers on both the suction and discharge sides. These air chambers absorb the excess at the time of maximum flow and discharge same at the time of minimum flow, thus keeping the liquid in the discharge pipe moving at a uniform velocity and preventing the shocks which would occur if no air chambers were provided. The advantages claimed for this type of pump are that it has the same characteristic positiveness as a piston pump, but without the objectionable features such as numerous valves, ports, internal packing, friction, etc. It has the simplicity of the centrifugal pump, and is more efficient, it being claimed that the best centrifugal pump installations can be operated inefficiently while the cycloidal pump if properly installed cannot be inefficiently operated. The catalogue is fully illustrated and contains a large amount of information on the subject of this type of pump.

SINKING has begun at the mine which is to be below the floor of the Mines and Metallurgy building at the Panama-Pacific Exposition, and the superintendent, Mr. Edward Steidle, of the U. S. Bureau of Mines, is as busy as though a new Homestake were in process of development.

EXPERIMENTAL WORK with the Malm process at the Bunker Hill & Sullivan mill at Kellogg, Idaho, has succeeded to the extent that it has been demonstrated that technically the process is workable. Mr. Stanly Easton and his staff are now resolutely attacking the larger problem of where and how the process can be used, if at all, to produce a profit.

DAMAGE from underground water in the oilfields is a matter of serious public concern. The California State Mining Bureau has taken the initiative in submitting to the Legislative Counsel Bureau memoranda for preparation of a bill for an act providing for formation of districts empowered to levy a special tax and to employ assistants to study and abate such damage. When the bill is put in form, it will be submitted to oil producers and others for criticism.

THE always active Chamber of Mines and Oil at Los Angeles has undertaken the publication of a monthly bulletin of which Mr. J. Nelson Nevins is to serve as editor. The first number, now at hand, is attractive and readable. With the backing of the Chamber, Mr. Nevins will, we hope, be able to continue indefinitely the work he has so well begun. Such publications serve a very useful purpose in stimulating local interest in mining and in securing from business men of the community a friendly hearing and discussion of mining problems.

A SLIGHT ambiguity crept into the excellent article upon 'Application of Jigs to Gold Dredging,' by Mr. James W. Neill (not J. W. Neil) as printed November 28. The saving quoted, 38 cents per yard of gravel jigged, is really figured on the total amount of gravel handled by the dredge during the time the jigs were running, that is, 448,000 cubic yards, bank measurement. In fact probably not more than one-third of the gravel passed over the sluices and perhaps two-thirds of that which was jigged; the saving though was figured on bank measurement.

DECISION by the Register and Receiver of the Coeur d'Alene Land Office in the Star Silver Lead contest is in favor of the company and against the Forest Service. The point at issue was as to what constitutes valid discovery. The decision was that while "such a discovery as is usually required of mineral applicants had not been made," the evidence of good faith, the showing as to mineral character, and the well known mineral character of the adjoining lands, was sufficient to pass the application to patent.

CALIFORNIA ENGINEERS are taking an active part in the Belgian relief work. The efforts of Mr. H. C. Hoover and Mr. Edgar Rickard in London are being supplemented by vigorous work on the coast. The San Francisco Engineers Club contributed $280 directly to the fund, while probably every engineer has made one or more personal contributions. The necessities of the Belgians have touched hearts around the world. Among papers coming to our exchange table this week, those from Tokyo, Auckland, and Lima, to mention three places widely scattered, contain acknowledgments of contributions toward local funds.

WHITE ISLAND, described on another page as an important source of sulphur, was recently visited by an exploring party from New Zealand which reports that the immediate cause of the destruction of the camp of employees of the sulphur company was an immense landslide. The buildings were on the floor of the old crater and were buried by a mass of rock from an overhanging cliff, and mud from a recently drained lake. It is supposed that the exciting cause of the landslide was an earthquake, as several shocks were felt on the mainland at the time. Earth movements, due to volcanic disturbances, have been particularly numerous in New Zealand of late.

MINING problems are, in many particulars the same regardless of the material that is broken and hoisted, and one of the best features of the later development of the American Mining Congress is that it is really bringing together men prominent and successful in widely varied lines of mining. This year, meeting in Arizona, famous for its gold and copper mines, the Congress was presided over by Mr. Carl Scholz, the head of the Rock Island coal interests and an able engineer

who has been active in many of the efforts to better mining conditions both technologically and industrially. We are glad to note that Mr. Scholz reports the financial position of the Congress to be better, and we trust that the next and succeeding years may see still further improvement.

APROPOS of a story recently told by Mr. J. F. Kemp reciting that Mr. J. H. L. Vogt once remarked that there are two types of professors, those who are 'privy counselors' and those who are 'uncles,' our New York contemporary patronizingly remarks that Mr. Kemp will himself in time come to be known as 'Uncle Jim.' This is somewhat amusing, our colleague evidently being quite unaware that to all his students the beloved Columbia professor has long been known as 'dear old Jimmy.' There is a third and smaller group of professors, those whom their students regard with affection as inspiring and helpful elder brothers, and the professor of geology in Columbia is one of the finest examples of this class.

AS A COSMOPOLITAN publication the new *Mine Workers Journal,* published in English, Italian, and Slavic, has a wide field of usefulness. Reaching as it does an element of labor, which in large part is being schooled in the ways of America, the *Journal* has an opportunity to play an important part in the molding of the correct viewpoint; and the making of a better class of citizens from the thousands of laborers who come annually to work in the mines of America. We trust that in formulating this broad policy the *Journal* will build nobly on the foundation of "justice, organization, and education," and that narrowness, vindictiveness, and inflammatory speech will not displace broad thought, lofty morale, and a less bellicose attitude toward those who make mining possible. Let the newly arrived workman know that America is not a hotbed of anarchy, industrial warfare, and oppression, but a land of equal opportunity where a great percentage of the employers of today were the laborers of yesterday.

AMONG papers read before the American Mining Congress at Phoenix were a number that dealt with problems of the coal mining industry. We reproduce that of Mr. George H. Cushing, the well informed editor of *The Black Diamond.* Mr. Cushing presents the facts about a serious situation, but they are facts so well known to men in the coal industry that he probably does not realize how striking they will appear to metal miners. Here is one of the great basal industries of the country in a chronic condition of disorder, an expendable and necessary resource of the country being wasted, capital dissipated, and men subjected to hardship and unnecessary danger—and the main obstacle to better conditions is a misinformed public opinion which prohibits the coal companies from any effective form of cooperation. To those familiar with coal mining, such national disasters as the long-drawn-out strike in Colorado, now fortunately declared off, are inevitable incidents in the struggle to regulate in some fashion an industry which the law says must not be regulated. It will do metal miners good to become familiar with coal mining problems, and, having done so, to ask themselves whether there is not enough similarity with conditions in copper mining and the petroleum industry to warrant all working together to bring regulation within the light of reason. It may be difficult to define reasonable regulation, and we are undoubtedly suffering in some instances from too much regulation, but in those industries such as bituminous coal mining, where all forms of regulation are absent, the public is also a heavy loser.

ANNOUNCEMENT that the Butte-Duluth mine, at Butte, which was developed by Mr. A. B. Wolvin, has been sold by him to the Hayden, Stone & Company interests for a price said to be $4,500,000, is an event of importance in the copper-mining world. A large tonnage of silicious ore containing chrysocolla and other oxidized minerals of copper has been developed, and a 100-ton leaching plant was built and operated for some time. Many difficulties developed in the leaching plant, and early this summer it was shut down. It has been announced that a successful leaching process has been developed to treat the oxidized ores of the Utah Copper Company, and presumably this will now be used at the Butte-Duluth, since it is the policy of the Hayden-Stone enterprises, under the management of Mr. D. C. Jackling, to develop a standard form of practice for their properties, so far as this is feasible. The rapid growth of this organization as a metal producer is only comparable to that of the United States Smelting, Refining & Mining Company, which some years ago similarly developed in the space of a few years into one of the most important organizations in the mining and metallurgical field in this country.

NICKEL

Nickel is one of the commonest mining constituents of igneous rocks, especially those high in magnesia, and the frequent association of its ores with magnesian rocks, such as serpentine, is well known. The average content of nickel found in nearly 300 different analyses of igneous rocks, made by the United States Geological Survey, is given by Mr. F. W. Clarke as 0.0274 per cent. This would indicate that it is one of the most abundant of the useful metals, yet nickel ores are mined in comparatively few places throughout the world, the antipodean districts of Ontario, Canada, and New Caledonia having almost a monopoly of its output. Because of its use in the manufacture of armor plate and other munitions of war, the present catastrophe in Europe is commonly supposed to have stimulated the production of nickel, but reports from Canada indicate that the Canadian Copper Company, the principal producer, is decreasing its output rather than increasing it. This, together with the fact that a strong financial group which last year made preparations to develop an extensive tract in the same district discontinued its operations after developing a large tonnage of workable ore, would

seem to indicate that the supply of nickel is ample to meet present needs. Markets, rather than depesits, are in demand. The world's output more than doubled between 1906 and 1912 and seems well able to keep pace with the growth of consumption.

So much has been written about the operations of the International Nickel Company, with its mines and smelter at Sudbury, Ontario (operated by the Canadian Copper Company), and its smelter and nickel refinery in New Jersey; the Mond Nickel Company, with its mines and smelter in Ontario and its refinery in Wales; and the companies that operate in New Caledonia, that they are fairly generally known, and to attempt to summarize their features would require too much space. It is not so generally known that there is a not inconsiderable production of nickel, chiefly in the form of nickel salts, from ores mined in this country. In a valuable paper which has attracted less attention than it deserves, Mr. Anton Eilers has pointed out that the blister copper produced at the Tacoma smelting plant contains 770 pounds of nickel in 100 tons of blister, that from the Omaha plant 944 pounds, that from the Nevada Consolidated plant 64 pounds, from the Garfield plant 40 pounds, and from the Mountain Copper plant 111/2 pounds. We further understand that the blister from the El Paso plant, chiefly derived from the Chino ore, also contains notable amounts of nickel. This nickel is recovered by evaporating the electrolyte of copper refining plants, and the amount thus recovered in 1913 is stated by Mr. F. L. Hess, of the United States Geological Survey, as equivalent to 481,565 pounds of nickel. A little known producer is the United States Nickel Company, which refines matte shipped from Europe to its plant at New Brunswick, New Jersey.

There are many places in which nickel occurs in this country. The old Gap mine, in Lancaster county, Pennsylvania, closed for the past twenty years, was a noted producer in its day. The Mine La Motte, in Missouri is well known for the nickel which occurs with the pyrite associated with its lead ore. Nickel ores occur in Douglas county, Oregon, and near Webster, North Carolina, but have not yet been profitably exploited, while the deposits at Lovelock, Nevada, which were once regarded as promising, proved disappointing. Quite recently a deposit was reported near San Diego, California, but apparently, as elsewhere, the tonnage of ore available for mining has not yet been shown to be sufficient for profitable exploitation.

The many occurrences of nickel ores in Europe have of recent years had little more than mineralogical interest, as the output has been small. The Flaad mine, Saetersdal, Norway, is one of the best known, and a recent consular report states that in 1913 it shipped 28,000 tons of ore to its smelter at Evje for treatment. The same report states that the Ringerike plant, near Christiania, handled 19,000 tons of ore, and that the refinery in Kristiansand produced 1,200,000 pounds of nickel during 1913. As this is the only plant using the process patented by Mr. Victor Hybinette, a brief description of the method in use will be worth while.

Copper-nickel matte, produced in the ordinary way, is ground, roasted, and leached with dilute sulphuric acid, the operations of roasting and leaching being so controlled that most of the copper is dissolved out without removing much of the nickel. By repeating the operation and finally treating with hydrochloric acid, the nickel-bearing material is freed from copper and can be smelted to yield nickel anodes for further refining by electrolysis. The copper is crystallized out of solution as bluestone, and is free of nickel until the nickel content of the mother liquor becomes too high, when the whole is evaporated to dryness and calcined to break up the sulphates. On leaching the calcine with dilute sulphuric acid the copper is again largely dissolved out and the nickel left behind. It was at one time reported that the Hybinette process would be used by the new company in the Sudbury district, already mentioned, but later this was denied. The Mond process was described in the *Press*, September 13, 1913.

Nickel finds its chief application in the production of various ferro-alloys, used in the manufacture of armor plate, automobile parts, and other objects in which hardness and toughness must be combined. Nickel steel is even finding application in structural work, and the new Quebec bridge is being built of it. It is interesting in this connection that the occurrence of nickel in iron ores is common, the best known instance being the mines of the Spanish-American Iron Company, in Cuba, where the average nickel content of the ores is a little over 1 per cent. As the large steel plant of the Maryland Steel Company, near Baltimore, uses these ores exclusively, smelting many thousands of tons per year, this is an important factor in the consumption of ferro-nickel alloys. Mr. H. W. Turner last year described the occurrence of nickel ores associated with iron in the Ural region of Russia, and many other instances might be cited. The special alloys of nickel are well known and scarcely need any detailed comment. Its use for nickel plating is the most important application of the pure metal. Of recent years there has been a great increase in the use of aluminum and its alloys for domestic purposes, and it seems not unlikely that the use of nickel-plated objects is likely to decrease rather than increase, except in the case of nickel-plated plumbers' fittings, for which there is a growing demand. An important field is the growing use of monel metal, an alloy of about two-thirds nickel and one-third copper, which has a remarkable combination of properties, being strong, very ductile, and non-corrosive. This alloy, which was introduced but a few years ago, has already created a large field for itself and seems likely to have increasing application. It will have been seen that there is plenty of nickel in the world to meet our requirements, and conservation is not likely to need to concern itself with this metal for a long time yet, except in so far as the present rather abnormal relations of mining, smelting, and consumption may be a factor in international economics.

LOOKING FORWARD

Among the pleasant features of the meeting of the American Mining Congress at Phoenix, Arizona, this week was the reading of a letter to that body from the President of the United States, Mr. Woodrow Wilson. In these days of numberless organizations for promotion of causes and of almost unlimited demand upon the President for his sympathy and support, the sending of such a letter is notable in itself. It is even more significant that the President shows a real knowledge of the problems and work of the congress and a keen sympathy with its purposes. The work of the congress in securing establishment of the U. S. Bureau of Mines and the prominence given both by the bureau and the congress to introduction of safer methods of mining, commend themselves to both President and people. The President's letter follows:

"To the Members of the American Mining Congress: I regret exceedingly that, owing to the press of circumstances, it will be impossible for me to greet you in person at the seventeenth annual session of the American Mining Congress at Phoenix, Arizona.

"I am well aware of the important part played by your great organization in the creation of our Bureau of Mines, and am sure that the good work of that bureau in attempting better to safeguard the lives of the two million men employed in the hazardous mining and metallurgical industries will continue to redound to your credit as well as to the credit of the bureau itself. It will always be a tribute to your foresight and energy that this new federal organization, in the short period of its existence, with the kindly co-operation of the states and their agencies, has been able by persistent and intelligent effort, to turn an isolated local movement for greater safety into a great national movement for 'safety first,' and has already gone beyond the mining industry into every industry of the country. I venture to say that thousands of lives have been saved by that movement, and that many thousands more will be saved in the future.

"Gratifying as the results of this life-saving campaign may have been, however, there is still vigorous work for your congress to do. I am informed that during the last year more than 3000 men were killed and 100,000 injured in the mining and metallurgical industries of the country. At the same time those in authority tell me that from their observation and experience one-half of such deaths and three-fourths of such injuries may be regarded as easily preventable.

"I suggest this situation as an opportunity for further endeavor on your part to cut down this excessive toll of death and of injury. I can assure you of the fullest co-operation of all the proper governmental agencies, also of my earnest desire for your active and continued assistance.

"There is one other problem connected with the mining industry in which the federal government is vitally interested, and that is, proper conservation and proper use of the mineral resources of the nation. I realize that you, too, are interested in this problem, and I wish merely to call it to your attention because of its fundamental importance to the present and future prosperity of the nation. I am happy to say that the profligacy of the past in the use of these resources is not being continued on so large a scale. There is, however, great opportunity for further reform along these lines, and in this your organization can be of invaluable service.

"Sincerely yours,

"WOODROW WILSON."

Addressing the American Mining Congress at Phoenix, Mr. J. A. Holmes, director of the United States Bureau of Mines, said:

"From the humanitarian standpoint no one questions the seriousness of the need of safety reform. Its economic importance is equally apparent, for during the past year more than 3000 men were killed and 100,000 injured in our mining and metallurgical industries.

"In connection with its investigation of explosives the Bureau has brought about what is little short of a revolution through the introduction of new type of low-temperature, quick-flame powders, designated as 'permissible explosives,' of which, during the past year, more than 25,000,000 lb. was used in the more dangerous mines of the country. As rapidly as facilities are provided there will be developed a 'permissible' series of safety appliances and methods in all branches of the mining, metallurgical, and other mineral industries, which, as their use is enforced by state inspectors, cannot fail largely to decrease fatal and other accidents. As indicating the efficacy of certain of these explosive investigations, the president of the company operating one of the largest metal mines of the country recently stated in a public address that the results of the Bureau's explosives work—incomplete as it was—had brought about an actual saving to this Company in this one mine of $80,000 yearly."

Speaking to the American Institute of Chemical Engineers at Philadelphia last week, Mr. George Otis Smith, director of the United States Geological Survey said:

"Coming down to bottom facts, the United States will profit by the European war only as the nation makes larger and wiser use of its mineral resources. Foreign markets in the main can be won and held only as the quantity or quality of the 'Made in America' product rivals that of the goods offered by the other producing nations. The buyer, whether he be in the Far East or in South America, wants the most and the best for his money. Yet it would seem a safe rule of national conduct that industry should begin at home, and therefore every industrial opportunity in America should be improved. If these opportunities are recognized and grasped every one of us can indulge in optimism."

Seward Peninsula and Its Mining Problems

By F. LYNWOOD GARRISON

To a geologist and mining engineer, one of the most impressive things about the Seward Peninsula is the highly mineralized character of many of its rocks. I am reminded in this connection of the remark of an old farmer's wife near Joplin, Missouri, when she said to me: "That land ain't good for nothing, so there must be mineral in it." This would seem to be the case on the Seward Peninsula; the soil produces nothing of value save pasturage for reindeer herds and a little not very nutritious grass that horses may eat in the summer. There is no timber west of the Kiwalik river. The ground is mantled with tundra and perpetually frozen to bedrock.

The rocks of the Peninsula are largely Paleozoic schists and limestones, and on the extreme west there are considerable areas of granite which is tin-bearing in spots. The streams draining these areas yield gold and tin respectively. The source of the gold is evidently the innumerable quartz seams and stringers that traverse the schists, especially when near their contact with the limestones. The 'stream-tin' no doubt has its origin in veins in the granite. No lode mining whatever is done on the Peninsula, and the miners and prospectors of the region are usually ignorant of what they call 'quartz mining'; in fact nothing not susceptible to a panning test interests them in the least. The intelligent people of the Peninsula, of course, recognize that its future, as an abiding place for man, depends upon the finding of lode deposits. The alluvials will be entirely worked out before many years, and if quartz mining does not develop, the country is certain to revert to the Eskimo and his reindeer.

The alluvial gold deposits of Northern Alaska may be conveniently divided into three general classes: (1) gravels in present-day streams; (2) high-bench gravels (the remnants of a former drainage system); (3) beach sands or bars such as those in the present beach at Nome. The extraordinarily rapid development of the Seward Peninsula was brought about during the years 1900 to 1904 by the discovery of very rich spots or concentrations of gold in the beach sands and the gravels of the creeks flowing into the sea near Nome. The resulting stampede is without parallel in the history of the world: unrivaled for its folly and waste. The Peninsula was flooded with the riff-raff of two continents who came, failed, and returned to civilization, leaving behind many monuments of their incompetence. Dishonest and impractical schemes flourished in those wild days and but few survived to reform and develop into more or less successful undertakings. Such a history cannot but leave an aftermath of discredit in any mining district—a reputation not deserved by the honest hard-working community that exists there today.

The phenomenally rich deposits that made Nome famous are now a thing of the past, and it is highly improbable anything of like richness will ever again be found in Alaska. The poor man may yet earn a good living in operating the leaner deposits still to be found in many parts of the Peninsula, but discouragement and discontent that the hard conditions of the country engender, become more and more evident every year. The federal government could unquestionably make matters easier for these excellent people by giving them better mining laws, roads, postal service, cheaper telephone and telegraph service, and decent and safe steamship service to the north coast of the Peninsula. As it is, the

HYDRAULIC ELEVATOR ON INMACHUK. HYDRAULIC ELEVATOR, PIONEER MINE, NOME.

HYDRAULICKING AT THE PIONEER MINE, NOME.

government is practising a paralyzing system of mistaken economy and the canker of politics is painfully evident.

Alaska ought to be governed by a non-partisan commission, subject only to Congress. Then, and only then, could the many and varied conditions peculiar to Alaska as a whole be properly studied and understood. We Americans are today living under the most inefficient and expensive form of government in the world, which seemingly becomes worse instead of better, although I do not myself believe that it actually is as bad as it once was, or as we sometimes think it is. We are slowly but surely learning the art of self-government, although as compared with Germany our government inefficiency is appalling. But if inefficiency be the price of personal liberty, I for one am willing to pay it.

I told my friends in Nome I believed that the government officials in Washington do not always know the whole truth about conditions in Alaska, and that the facts were often so befogged and juggled for political purposes that the public is at a loss to know what may be the real needs of that far-off dependency. I suggested to them a plan of co-operative publicity on their part to make known Alaska's conditions and desires, believing, as I surely do, that the government and public opinion will concede to all their reasonable demands once they are understood.

The world today is facing a steady decline in its production of gold. In 1912 it was $472,090,431; in 1913, $454,269,275, a decrease of $17,821,158. The production in the United States during the same period fell off $5,150,477 ($93,451,500 from 1912, as compared with $88,301,023 for 1913).

The ever-increasing demands for gold in commerce and industry must be met, not to mention the enormous drain on our gold resources the rehabilitation of Europe will require. Unless we once again resort to bi-metallism, new gold deposits must be found and old ones worked more economically. No part of the United States offers such opportunities for doing this as Alaska, and there is no disguising the fact that placer mining on the Seward Peninsula, if not all over Alaska, is surely but certainly declining, and except at Juneau, lode mining is yet in its incipiency.

I fully believe this discouraging outlook is needless and undeserved. Alaska is a white man's country, a territory gloriously healthy and undeveloped, in fact quite unexplored in places. But the natural difficulties to be overcome in its development are serious, and the encouragement of large capital is necessary. In fact, mining the world over is no longer a poor man's business; the cream of our mineral deposits has been fairly well skimmed, and in the future we must depend upon low-grade ores and relatively lean alluvial deposits, which cannot be worked without expensive equipment and large financial resources.

There is plenty of good coal in Alaska, but it costs something like a million dollars to open and equip a good modern colliery. How many individuals, or corporations, are there today ready to go into an enterprise of this kind? As long as fuel oil is as cheap as it is on the Pacific Coast, we may safely assume that no large coal operations are likely to be attempted in Alaska. The local demand is small and will not increase where water-power or cheap fuel oil may be had. In brief, Alaska cannot be developed without large capital, and to invite capital the government must first provide railroads and harbors, and not count the cost.

Alfred H. Brooks, of the U. S. Geological Survey, estimates that there are about 210 square miles, or 650,496,000 cubic yards, of gold-bearing gravels on the Seward Peninsula, averaging 3 feet in depth, which contain something like $300,000,000 in gold.* I am disposed to think that these estimates are too high as to value per cubic yard and too low as to area in square miles. The total production of gold on the Peninsula from 1897 to the present time has been something like $68,000,000.

But there are serious difficulties to be overcome in gold mining operations in this far northern country. The most important is the fact that the ground, as a rule, is frozen to bedrock, is mantled with a thick blanket of turf, called tundra, or 'muck,' which is a

*U. S. Geol. Survey *Bull.* 328, pp. 135-137.

most excellent non-conductor of heat. As a consequence the summer sun has little or no opportunity to thaw the underlying gravel. This 'muck' carries practically no gold, and the expense of removing and thawing it is a dead loss. A second difficulty is the shortness of the working season, which is usually reckoned as about four months, namely from June to October. It has been found, however, that with proper precautions a dredge may successfully operate until late in November and in some seasons begin as early as the middle of May. No doubt a well equipped and managed dredge, carefully protected from the weather, could operate a full five months, if not a little longer, under favorable conditions.

The question of fuel and power is usually a very serious one to overcome on the Seward Peninsula. Fuel is, or can be made, cheap enough on the coast, but without decent roads it becomes almost as precious as gold a few miles from the water's edge. During the early prosperous days at Nome, a little narrow-gage railroad was built from that town to a place called Lane's Landing, in the interior, a distance of some 80 miles. I am told it paid for itself in the first two years and earned a fair return thereafter until the federal government found it necessary to impose a tax upon this commendable enterprise of $100 per mile per year. In other words, instead of subsidizing, it actually penalized an institution that was doing much to develop the country. One may understand the logic of a policy that demands a moderate royalty on the gold produced from the public domain, but the wisdom of taxing to death an enterprise so important to a wild and undeveloped district is past finding out. The Kougarok district, which is tapped by this railroad, is one of the richest and most promising on the Peninsula. It contains some rich ground that is being worked at a fair profit by a number of small dredges, despite the enormous costs which they have to meet for fuel and power. Once this district is supplied with cheap hydroelectric power to operate the dredge, and fuel to thaw the ground, there is no doubt but that the number of dredges therein will be largely increased. Sites exist in the neighboring mountains which afford convenient opportunities for such power plants, and the rehabilitation and operation of this little railroad by the government should provide reasonably cheap fuel and supplies to the miners of the district.

A chapter might be written about the dredging operations at Nome. It may be said in brief that they have been, on the whole, financial failures, despite the presence of some of the richest alluvials in the world. A cursory inspection of these dredges here is depressing. They are great big machines that have cost a mint of money, but are today either partly finished, wholly idle, or are running so feebly that one fears to look at them too intently lest they stop altogether. These dredges are controlled chiefly by one organization, whose headquarters is in Philadelphia. This company, as far as I could ascertain, has no engineering staff, nor has it, apparently, followed a sound system of business management. As a consequence, its credit is impaired and its equipment is today little better than piles of scrap and a monument to incompeteney. In extenuation, however, of this deplorable condition, it should be said that the present management is acting as a sort of residuary legatee for several older 'busted' or decrepit concerns. The risky experiment of compounding failure without a drastic reorganization, sufficient new capital, and the best engineering talent, could bring about no other result. Moreover, the natural conditions for dredging on the Seward Peninsula are not easy, the ground is usually frozen to bedrock, the seasons are short, labor expensive, and the machinery must of necessity be the best and strongest that can be made.

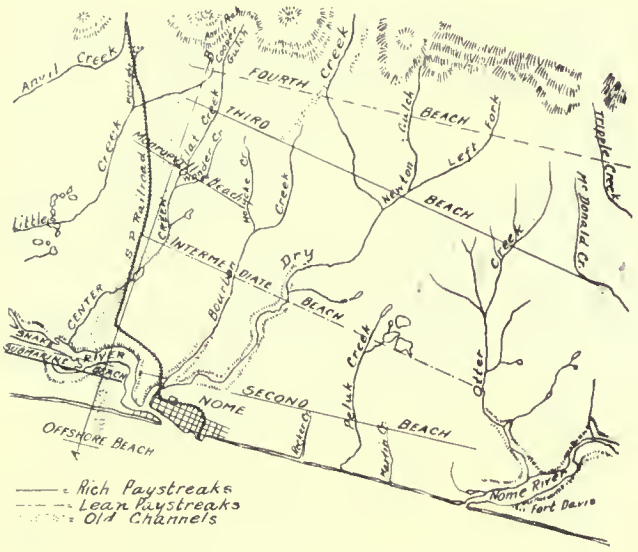
Dredging in the Council and Solomon districts appears to be fairly successful this year. Not having myself visited the districts, I cannot speak from personal knowledge. I understand, however, that at least one dredge on the Solomon river has been equipped with Diesel engines, which have given notable results as to efficiency and economy.

The Buck Creek tin dredge is reported to have done well this year, but some difficulty due to the European war has been experienced in disposing of its tin concentrate. Heretofore this has been shipped abroad for smelting, as there are no tin smelters in the United States. In this way, advances could be obtained on the product by the dredge people, and the capital necessary

QUARTZ VEINS IN BEDROCK, ANVIL CREEK, NOME.

to carry on the enterprise thus reduced. With the interruption of such shipments, some local smelting must be found or the dredge probably cannot continue operating next year.

Except for assessment work, no other tin mining appears to have been undertaken this year in any of the tin districts of the Peninsula. As tin is becoming almost a semi-precious metal, it is unfortunate that more



THE NOME BEACHES.

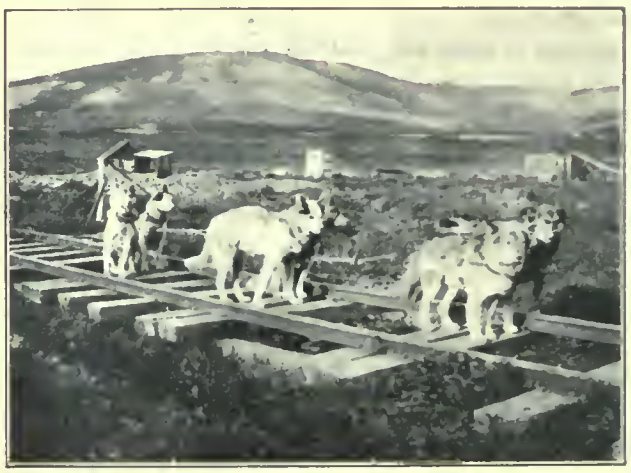
systematic prospecting is not being carried on in this promising region. Here again is the same old difficulty that has been encountered in all attempts to prospect the country—namely, lack of funds and experience.

The gold production by small operators appears to be, on the whole, steadily but surely decreasing with the exhaustion of the richer and more easily worked gravels. This is a real misfortune for the Peninsula, because miners of this class are the backbone of any gold-producing community, and as a rule they deserve every possible encouragement from both the federal government and the large operators who may be their neighbors.

Lode mining on the Peninsula has so far proved a failure, as no large rich outcrops appear to have been discovered. That workable lodes of gold and possibly other metals exist on the Seward Peninsula, I have not a particle of doubt. The miners of the region with but few exceptions, are unfamiliar with the character of the prospecting necessary to develop deposits of this class; in fact, the pan is their sole assay outfit, and the pick and shovel usually their only tools. The alluvial gold must have originated in veins, and such veins certainly do exist in the country rocks not far from the gravels in which the gold is found. A few years ago a small stamp-mill was erected near Nome, but it failed for the reason that sufficient ore could not be obtained to make it pay.

On the whole, the season of 1914 will probably turn out to have been a fairly good one. Last year few of the operators made anything; water was scarce because of light snowfall the previous winter and an unusually dry summer. As a consequence, the large ditch operators, like the Pioneer and Fairhaven, either just made expenses or had an actual loss.

Dredging operations in 1913 were not so seriously affected; some of the smaller plants appear to have done well. This year may have been a little better for the dredges, but on the whole it is doubtful if any of them are earning what they ought, or what the ground would justify, and until the Peninsula has good roads and cheap hydro-electric power it is doubtful if the dredging business will ever be on an actually sound and solid basis. It is now fairly up to the people interested in the Peninsula to work together in making their needs known, to get from the government what they require, and what I for one believe the United States will gladly give them once the facts are understood in Washington. The congressional delegate cannot be expected to do this for them, as he has other and more important things to attend to. The salvation of Alaska is in the hands



MOTIVE POWER ON AN ALASKA RAILWAY. ANVIL MOUNTAIN IN BACKGROUND.

of those whose interests are there; if they do not get together and make known the truth, so much the worse for their interests and Alaska.

THE TRANSVAAL CHAMBER OF MINES reports as follows for September:

Ore mined, tons	2,446,532
Sorted out, per cent	9.79
Ore milled, tons	2,288,939
Stamps working (26.44 days)	9,296
Tube-mills working	283
Duty per stamp-day, tons	8.97
Total gold yield	£2,875,983
Working costs per ton (50 companies)	$4.02
Profit	£989,859

GOLD AND SILVER BULLION received at the San Francisco mint in November was 305,629 and 75,559 oz., respectively, worth a total of $6,354,182. The coinage executed amounted to $2,120,000 gold, $122,000 silver, and $23,000 nickel. Coin, bullion, etc., on hand at the end of the month was valued at $259,581,566.

The Coal Trade Problem

By GEORGE H. CUSHING

*Modern coal mining requires an enormous and a constantly increasing investment. The exhaustion of coal reserves and the limited available acreages are increasing coal land values at an alarming rate. The people are demanding a refinement of preparation which is compelling the erection of costly coal preparation plants. Mine labor is continually demanding better wages.

To offset this constantly increasing investment, the operators are beginning to realize the extent to which they are forced to submit to a gradual but cumulative reduction in the selling price of coal. With rising cost of production and decreasing selling price, whatever margin of profit there once was in the coal business is now wiped out. The net results, as far as the present period is concerned, are that the coal trade, as a whole, has no undivided surplus—no reserve financial energy—upon which to draw to tide over the present period when losses must be encountered. Therefore, individual companies are passing into actual bankruptcy, while it must be confessed that the trade itself is in a state of constructive bankruptcy. To avoid the development of this general constructive bankruptcy into actual bankruptcy, the coal producer is induced to rob his own mine, which, of course, results in a lack of national economy as to fuel.

Bankruptcy of Mining Companies

Regarding the companies which actually pass into bankruptcy, the members of the coal trade who remain solvent see themselves in a peculiarly dangerous position. The conditions which threw the various companies into bankruptcy also leave those which remain temporarily solvent with no money and no credit with which to absorb into their own organizations the plants of those concerns which failed. Because of the absence of any surplus money, those now in the coal trade cannot absorb the properties which are thrown by forced sale upon the market. Still, those bankrupt represent an enormous investment and a necessary productive capacity. The mere fact of bankruptcy does not annihilate the properties, nor does it remove the national need for a great many of them.

The natural result is that the ownership of these bankrupt mines becomes vested, not in men already in the coal trade, but in business concerns outside of the coal trade which take the mines, not because they want them, but to protect interests which they have in fuel. Therefore, every failure of a mining company means, not the extension of the powers of some company already in the coal trade, but a gradual infiltration to the coal business of outside and really antagonistic interests. As coal men see it, it requires only some such event as that through which we are now passing to cause the crystallization or solidification of these outside holdings. When that comes, we will have what the people for so long have feared—a bituminous coal 'trust' or monopoly. With this the other operators and the whole people of the United States would have to contend.

Idle Time in Coal Mines

This curiously complicated and dangerous financial side of the coal trade is only one of the problems confronting the operator. Another, and a very serious matter, is the idle time, not only of the plants themselves, but of the men who work in those plants. Counting out of a full year 65 days for Sundays and holidays and 25 additional days for extraordinary holidays and mine accidents, there is left a potential working time for the mines of 275 days per year. The average made by all of the mines of the United States, the anthracite mines included, was 225 days. This means that the coal miner, on the average in the United States, lost in 1912 50 working days, or exactly two months. He worked 10 months out of 12, whereas he should work, of course, 12 months out of 12. Some of the larger producing states, like Illinois, Indiana, and Ohio, made far less than the average time. Illinois, the third largest producer of the nation, put in only 194 days, which is for that state a very high average. Indiana made 182 days, which is about the average for that state. Ohio made 201 days, which is a good average for that state. Thus the best of these three major producers lost 75 working days in 1912, or three months' time in 12. The others showed a loss to the workers of $3\frac{1}{2}$ or nearly 4 months in 12. This is a definite and serious loss of time to men, and it simply means this: At present the men are not making more than a fair daily wage. They are making good money when they get work, but the trouble is that they do not get enough work to cause their yearly income to be what they consider sufficient. The miners, as a consequence, are eternally striking for more money. Every time the industry passes through a strike it faces a further complication of the labor and the financial disorders of the coal trade.

That is to say, through and during the strike of the miner there is a temporary reversal of the price tendencies. Coal prices, due to a fear of a shortage or to an actual shortage, rise rather rapidly. This temporary period of high prices misleads a great many men who have a little money into the belief that such times are customary in the coal trade, and hence that the coal business is a good thing for them to engage in. These recurring periods of high prices due to strikes, therefore, constantly invite new competition into the coal

*A paper written for the Phoenix meeting of the American Mining Congress and printed with the preliminary program.

field. This additional competition is just so much additional waste. This constitutes one of the very serious problems of the trade.

Another big problem of the coal industry is in the matter of production. It has been said from time to time that the real difficulty is overproduction. Of course, everyone recognizes that there cannot be any such thing as actual overproduction of coal without there being an accompanying and actual waste of coal. In the old days there was real overproduction, and in those times the excess, represented mainly by fine coal, was dumped on the ground and not infrequently was used as ballast for railways. The time when such things were possible in the coal trade has long since passed. No actual overproduction occurs now. The trouble of the market does not come from that source. However, there is potential overproduction, or the capacity of the mines to produce from 25 to 40% more coal than is actually being bought and consumed. It is this potential overproduction—expressed eloquently in the fact that all mines of the nation are idle two months in the year—that brings the constant pressure upon the market. No market can possibly be strong, or even reasonably stable, while there is the constant possibility that at any minute the mines may throw upon the market one-sixth more coal or one-quarter more coal than the market can possibly absorb. It is this potential overproduction, induced mainly by periods of labor disturbance, that is causing one of the biggest problems of the coal trade.

But there is in the matter of production some difficulty more substantial than merely a potential overproduction. That is, untimely production. That is to say, as is well known, there is in certain months a demand for the steam sizes and practically no demand for the domestic sizes. Still, the domestic sizes must be made in order to get the steam coal. In the remaining months of the year, the situation is reversed. When steam demand is predominant, domestic production is untimely. When domestic demand is predominant, a certain percentage of steam production is untimely. The coal trade recognizes that it has no mechanism and certainly no system of temporary storage that will take care of the surplus of any period until the time comes around when that coal is going to be required.

Closer Sizing Increases Trouble

This difficulty of sizes is emphasized by present tendencies in the mining and marketing of coal. It is literally true that as the number of sizes made at the mines is increased, automatically the proportion of the mine's output which goes, because of its size, into the steam trade, increases. That is, the domestic trade today wants the larger coal; the steam trade is forced to absorb the smaller coal. Every new act of mechanical preparation increases the percentage of small coal through the breaking up of the lumps. This automatically increases the amount of coal which the steam trade must absorb, also every act of preparation increases the production of the smallest of these various sizes. It is the rapid increase of these smaller sizes that is causing the complication of the coal trade. This is so for the reason that the production of the fine coal is an increasing factor due to the fact that mechanical handling and re-screening plants are being built faster than are modern furnaces in which to burn these fine sizes of coal. The problem therefore, in production—the real problem—is what to do with the fine coal.

Several suggestions have been made along that line. One is that the fine coal should be stored in the winter time to take up the excess demand in the summer time. There involves the difficulty that an adequate storage plant would cost millions of dollars and the coal trade, because of the financial conditions already outlined has not enough credit with the banks to permit it to borrow all the money that would be necessary. The coal trade sees the possibility of making this reform, but it is without the financial resources to take advantage of so big an opportunity.

No Capital for Storage

Another big difficulty in the same direction is that these storage plants requiring enormous sums of money cannot be created by individual enterprise, but must spring from a co-operative movement, which the spirit of America at the minute opposes, and which is, in fact, directly contrary to the laws now operative and at present being enacted at Washington.

Another suggestion that has been made has been that briquetting plants should be established at central points in mining districts to convert into the domestic sizes a certain percentage of this fine coal. However, a briquetting plant costs an enormous sum of money. Moreover, the cost of manufacture of briquettes is close to a dollar per ton. The coal trade sees that there is not a difference of a dollar per ton between the price of the rejected fine coal and the market price of the prepared coal, at which price briquettes would have to sell. Because of the absence of enough margin between the selling price of the raw coal and the selling price of the manufactured product, the coal operators cannot induce men of money to lend them enough to engage in briquetting as a general practice. Besides, briquetting on any such scale as is here presupposed would be an enterprise entirely too big for individuals, and hence would require a co-operative movement against which the objections have already been enumerated.

Another suggestion which is common is that seeing the need for by-products obtained from the manufacture of coke, the coal trade should build coking plants and ship to them the excess of fine coal. This is an attractive suggestion from a national point of view and has a great many merits from that of common sense. The people who should naturally do the coking of the country are the coal men. But it is difficult to see how they can do so.

For example, an ordinary small sized coke plant costs $1,000,000. To handle the excess fine coal at any one

producing district it would take a coking plant which, to do nothing more than to distill the crudest possible by-products of coal, would cost $5,000,000. To get another plant that would work over those by-products into marketable articles would cost an equally large sum. If the cost of this plant for one district—namely about $10,000,000—be multiplied by the number of coal producing districts in the United States, an outlay, at the very start, of not less than $100,000,000 is indicated: the actual, necessary outlay possibly amounting to several times that amount.

It is submitted here that if individual coal companies have not the credit with which to borrow the money to carry on their ordinary business—for this reason many coal companies are constantly going into bankruptcy—there is no hope that coal men can borrow the untold millions of dollars necessary to go into the coking business on any such scale as a solution of the fine coal problem would involve.

At the same time, the coal trade problem for the United States must be solved. This country cannot, for long, endure the loss of coal involved in the present extravagant methods. It cannot, for long, endure the economic loss incident to the enforced idleness of over a million men for several months out of every twelve. It cannot endure the financial loss incident to a constant overproductive capacity in its second industry of 40%. Some solution of the problem, therefore, must come and must be started quickly.

The purpose of this article is to show that the primary need is for some form of co-operation that will put a financial foundation under this business that is sufficient to permit the beginning of some of these needed reforms. For example, briquetting, coking, and the storage of surplus of certain periods should be provided. But to get these things there must be co-operation. Before co-operation can be effected, the consent of the government must be obtained. The first need, therefore, is the consent of the government that the coal men may work together to solve a national problem regarding the nation's supply of fuel.

After that is permitted, credit and the money that is necessary to carry on certain of these reforms will follow. Then there will be a little more profit in the trade than there is now. This will create a surplus, or something of reserve financial energy which will permit the coal trade to extend, naturally, into those refinements of coal mining, namely, coking and recovery of the by-products. In giving the operator that money the public will likewise give greater earning capacity to the miner; more employment to a greater number of men; bigger and better business for various communities, and all of these things spell definite national progress.

The one barrier between the situation as it is and the situation as it might be and ought to be, is the governmental prohibition of anything like sensible co-operation.

White Island Sulphur Deposit

By W. D. HORNADAY

One of the largest and most remarkable sulphur deposits in the world is situated on White Island, which is a volcanic mountain that belongs to New Zealand. Although this island is several miles from the mainland of New Zealand, its thermal wonders attract thousands of interested visitors each year. The first efforts to utilize this sulphur in a commercial way were made in 1886. At that time the island was so isolated that the exploiters found it impossible to keep a working force. This, together with a lack of transportation facilities, caused the industry to be abandoned. In 1912 interest in the possibilities of the industry was revived. What is known as the New Zealand Sulphur Co. was organized with a capital working stock of $125,000 and a reserve capital of $100,000 for the purpose of acquiring and operating the deposit. Since then a well equipped permanent camp has been established, retorts for the refining of the sulphur erected, and other facilities installed for handling the product. The output of the plant is now about 1000 tons per month, and this is to be greatly increased. Excellent arrangements are in effect for the transportation of the product to the different ports of New Zealand, Australia, the Straits Settlements, and islands in the Pacific Ocean. It takes about 30,000 tons of sulphur annually to supply the Australian market, and it is planned that all of this shall come from the deposit on White Island. The annual consumption of sulphur in New Zealand is about 3000 tons, and it is increasing.

WHITE ISLAND SULPHUR DEPOSIT.

The boiling lake upon White Island is one of the great awe inspiring sights of New Zealand. It is surrounded by precipitous cliffs which give the lake the appearance of being the crater of an active volcano, which it doubtless is. After the Company had spent $100,000 in preparation for mining, a volcanic disturbance wrecked the camp and killed 10 men, as reported in the *Press*, October 31.

A Plan for Reviving Hydraulic Mining

By C. S. HALEY

As the early history of the American occupation of California is forever associated with the gold-hunters of 'forty-nine,' so is the economic development of the state indissolubly bound up with the development of hydraulic mining. During the period from 1848 to 1860 and later, the working of gravel by hand was extremely easy, owing to the thousands of acres of light gravel whose shallow banks held the concentrated burden of the ancient eroded auriferous channels. After the cream had been skimmed, however, the miners turned their attention to the deeper heavier gravels, and the hydraulic giant was evolved. Its development, and the progress of the mining industry under its use, are not within the scope of this paper. It is sufficient to say that in 1876, when hydraulic mining had obtained its maximum growth, there was over $100,000,000 invested in plants, equipment, and property, and the annual yield was from $11,000,000 to $13,000,000. Compared with the $50,000,000 to $80,000,000 of the annual yield before 1857, this does not loom very large; but without it, during the decade of 1870-80 the annual yield of California gold would have been insignificant.

Growth of Agricultural Interests

While the hydraulic mines were flourishing, however, the owners apparently overlooked the growth of another industry, which was one day destined to drive them from their own field in the battleground of the courts. The broad valleys where the mountain rivers debouch into the Sacramento and San Joaquin rivers teem with fertility, and these soon attracted the attention of immigrant farmers. Land which the miners could originally have bought for little or nothing and held as a perpetual dumping ground steadily mounted in value, and its increasing productivity permitted the farming interests gradually to overshadow the mining.

The accumulation of débris in the rivers was long a source of annoyance and considerable damage to the farmers. Even during the days of ground-sluicing, the great flood in the winter of 1862 covered the richest bottom and orchard lands along the Bear and the Yuba rivers with tons of débris from the gold washing. At this time, however, mining was regarded as the more legitimate and powerful industry, and but little protest was made. As the strength of the agricultural interests grew, protests against the overloading of the rivers became more and more frequent and more powerful, until the struggle culminated in the famous 'Sawyer decision,' on January 23, 1884. This decision, handed down by the U. S. Circuit Court, in the case of Edwards Woodruff *v.* the North Bloomfield Gravel Mining Co. *et al.*, wiped out at one blow property values exceeding $100,000,000, and indefinitely postponed the addition to the world's wealth of what has been roughly estimated at from $500,000,000 to $1,000,000,000 in placer gold.

The Sawyer decision was, however, but the culmination of a long struggle. The farmers of Sutter, Yuba, Sacramento, and a few other of the valley counties, organized in the early seventies the Anti-Débris Association, to take their struggle into the courts. They were opposed by the once powerful California Miners' Association, and the struggle was long and bitter. The story of the fight from the miners' point of view, is especially interesting and from it one can gain an idea of the principles for which each side was contending. To that end, I quote from a circular issued by the Miners' Association on June 15, 1883, which briefly reviews the then existing situation.

History of the Litigation

"* * * I deem it proper to revert to the services of this Association in the defence of the mining industry. The first case of importance was that of Keyes *v.* Little York and 38 other defendants, begun July 29, 1876. After a long trial, wherein the best legal and engineering talent in the state was employed, a judgment was rendered against us. We appealed the case to the Supreme Court of California, where it was reversed on a point raised by demurrer, on the ground of misjoinder of parties defendant.

"The City of Marysville then brought suit (September 15, 1879) against the North Bloomfield Gravel Mining Co. and 32 other companies. They included about 200 other persons as defendants. The defendants appealed to the Supreme Court from the injunction issued in that suit and also demurred and applied for change of the place of trial. The motion was refused and an appeal was taken to the Supreme Court, where it is now pending.

"* * * Simultaneously with above action (State of California *v.* Miocene Mining Co.) the Attorney-General commenced suit (June 28, 1881) against the Gold Run Mining Co. of Placer county. Defendants, through the counsel of the Association, demurred and answered. The trial came on in October 1881 and occupied the court 60 days. The presiding judge (Temple) rendered a decision June 12, 1882, sustaining the injunction, with a qualification that on a proper showing of the construction of dams to restrain the coarse material he would entertain a motion to dissolve the injunction. The point raised on demurrer as to want of authority of the Attorney-General to use the name of the state, was not decided, but referred to the Appellate Court. Neither party fully acquiesced in the decision. Defendants appealed to the Supreme Court. Appeals were taken by both, and the day of argument is not yet set.

"Then the County of Yuba sued the Excelsior Water & Mining Co., the Eureka Lake & Yuba Canal Co. Con.,

the Blue Tent Consolidated Hydraulic Gold Mines of California, Ltd., and the Yuba River Gold Washing Co. The last had further time to plead, which is now about expired. Injunctions were issued in all these cases, *ex parte* and without notice to the defendants. Then came the suit of the County of Sutter *v.* J. F. Hickey *et al.*, commenced April 14, 1882, in the county of Colusa. The defendant's mine is in Nevada county. Also about the same time a suit against the Birdseye-Creek Co. of Placer county.

"The last action brought is that of Edwards Woodruff *v.* North Bloomfield Gravel Mining Co., Milton Mining & Water Co. and some eight other companies. It is substantially of the same nature as the others, praying for a perpetual injunction. Woodruff being a citizen of another state the suit was brought in the Circuit Court of the United States, Judge L. B. Sawyer presiding. Defendants demurred on ground of misjoinder of parties defendant. The demurrer was argued by the ablest counsel in the state, occupying the court two weeks, and was overruled. The testimony is now being taken before commissioners for the main trial in September.

"All of the above actions have been defended by the Miners' Association, at an aggregate expense of not less than $200,000."

The Fatal Decision

The decision in the case last referred to may be quoted in its principal part as follows:

"And that the defendants herein * * * and each and all of their servants, agents and employees, are perpetually enjoined and restrained from discharging or dumping into the Yuba river, or into any of its forks or branches, or into any stream tributary to said river or any of its forks or branches, and especially into Deer creek, Sucker Flat ravine, Humbug creek, or Scotchman's creek, any of the tailing, boulders, cobble stones, gravel, sand, clay, débris, or refuse matter from any of the tracts of mineral land or mines described in the complaint. And also from causing or suffering to flow into said rivers, creeks, or tributary streams aforesaid therefrom, any of the tailing, boulders, cobble stones, gravel, sand, clay, or refuse matter resulting or arising from mining thereon. And also, from allowing others to use the water supply of said several mines or mining claims, or any part thereof, for the purpose of washing into said rivers and streams, any earth, rock, boulders, clay, sand, or solid material contained in any placer or gravel ground or mine. * * * That the defendants, or either of them, may, at any time hereafter apply to this court, upon due notice to the complainant * * * for a modification or suspension of this injunction * * * upon any showing which the court may deem sufficient that the conditions have been so changed that the discharge of such mining débris by said parties or party * * * may be resumed or otherwise conducted, so as not to create or continue the nuisance complained of, or a nuisance of similar character, and so as not to injure or damage said complainant, or upon any other grounds hereafter arising satisfactory to the court. And for the purposes aforesaid, the court hereby reserves the power to modify or suspend said injunction in whole or in part, as the exigencies and equities of the case hereafter arising, may require."

The result of the Sawyer decision has already been stated. The decree of the court was not against hydraulic mining in name, but against dumping the débris into streams and ravines. On the large mines operations were suspended, as injunction after injunction closed them down, and property worth millions went into disuse and decay.

Secret Mining and Spies

Of the smaller mines, however, many persisted in continuing to work, and the Anti-Débris Association, composed of farmers of the valley, carried on an organized opposition to hydraulic mining. Long and costly litigation resulted, and continued for years. As injunctions had to be secured in each and every case, the Anti-Débris Association had to keep men in the field securing evidence, and among the miners feeling ran high against these 'spies.' Gradually, however, the operators gave up the struggle. Thousands of people were thrown out of employment, the gold production of the state dwindled, and property values in the mountain counties were decreased by millions. For about nine years, this continued, growing from bad to worse. A review of the situation, already growing serious in 1881, by the Miners' Association, sets forth the losses resulting from the closing down of hydraulic mining in very emphatic fashion. I quote some extracts, which may throw some light on the attitude of that body.

"California has produced (1848-1880) * * * between $1,100,000,000 and $1,200,000,000 of gold, of which very much the larger portion has come, either directly or indirectly, from the ancient or pliocene river channels. * * * As the (surface) placers became exhausted, the miners naturally turned their attention to the sources from which the placer gold had been derived. Commencing in 1851, they have steadily prosecuted the development and working of the ancient river beds, until the yield from them amounts annually (1881) to a sum varying from $11,000,000 to $13,000,000, with the prospect for many years to come of equally great returns. In order to accomplish this result, the expenditure of large sums of money has been required in building dams, canals, and tunnels. The Bloomfield and Milton companies afford a good illustration of the large capital necessary for the successful development of such properties. Work was vigorously commenced on the mines of these companies in 1854, since when about $1,000,000 has been expended—all representing capital account until 1878, when their works were finally completed. All this $4,000,000, with unimportant exceptions, was furnished by stockholders resident in California.

"We roughly estimate the present actual value of these mines in California to be $80,000,000; adding to this the property whose value is dependent on the existence of these mines, there results a total present value of probably $100,000,000."

These statements, made in 1881, show how strongly the danger of extinction of the hydraulic mines was felt at that time. They also serve to emphasize what a tremendously important effect upon the economic progress of California hydraulic mining has had. To continue:

"In the early days of placer mining, when there were literally hundreds of thousands of miners washing the soil in every gulch, ravine, and river of the Sierras, the aggregate quantity of material washed into the rivers must have exceeded the amount which by improved, but similar appliances, is now being placed in them. * * * The gravel channels of California have yielded in the past nearly $1,000,000,000 of gold, which has been a mighty force in bringing about the existing prosperity of the civilized world. A still greater quantity remains in our unworked but developed channels, ready for extraction. * * * Can California—can the United States—suffer this great treasure to be forever locked up in our mountains? * * *

Extent of Damage

"The State Engineer in January 1880, after detailed and careful examination, reported that 43,546 acres of land had been depreciated in value by the flow of mining débris, with a resulting damage amounting to $2,597,635. * * * That the Feather and Sacramento rivers have been injured is conceded by all, but we have the official statement of Captain Eads—as competent an authority on such matters as can be found in the world—that if the flow of heavy sands is kept from entering those streams, they can easily, by proper treatment, be brought into excellent condition. * * * It seems to be taken for granted that we have to deal with engineering problems more difficult of solution than have before been encountered. This is not the case, for both in France and Italy many of the rivers carry larger quantities of earthy material in proportion to the water than does the Sacramento. In these countries no great difficulty has been experienced in protecting the lower lands and rivers.

"From the examinations and reports of our engineers, we became satisfied, several years since, that it was practicable, at a comparatively moderate expense, safely to store for many years to come all the injurious flow of mining débris in the Yuba, Bear, and American rivers by forming reservoirs by the construction of brush and stone dams in the bottoms and cañons of those streams. * * * the now famous 'Débris Act' was strongly advocated by both miners and farmers, who, in that measure, asked for state aid, so that the necessary funds could be secured to establish a thorough system of protection. In this legislation the miners showed their willingness to pay their full share of the burden, by being taxed in three different ways, and much more heavily than any other class. Under the operations of this act two restraining dams were built in 1880, one across the Yuba, and the other across Bear river, at a cost of nearly $200,000. The residue of the money procured by the taxes levied under the authority of the act, amounting to some $290,000, was spent chiefly in building levees, for the purpose of confining the rivers, so that they might, by a scouring action, deepen their beds."

The results of the court decrees already foreseen at this time have been stated above. For seven or eight years the industry was gradually paralyzed by the activities of the Anti-Débris Association in serving injunctions. Then, in the fall of 1891, the fight was taken up anew. At this time, a number of miners in Placer county, who had suffered from the closing down of the hydraulic mines, met and decided to call a county convention to see whether anything could be done to revive the hydraulic mining industry. This convention was called in Auburn, with the object of formulating a plan for a state miners' convention and memorializing Congress as to needed legislation for the industry. This state convention was called in San Francisco, and representatives of both the mining and farming interests were invited. Contrary to expectation, the meeting was entirely harmonious, and a common plan was agreed upon readily.

The basis of this agreement was the report of a government commission of engineers. This commission was appointed by a special act of Congress, upon suggestion of the legislature of California. It appeared from their report that dams and other restraining works could be erected in many of the cañons for the restraining of débris caused by future mining operations, as well as débris already in the rivers from former operations.

The convention of miners then asked Congress to accept and adopt the report of the Commission, and to take steps at once to put into practical operation the plan suggested, so that mining might be again carried on under specified conditions, and the débris restrained from the rivers and farming lands. The result of this was the so-called 'Caminetti Act,' introduced into Congress in 1892, and passed in 1893. It is under the provisions of this act that whatever hydraulic mining is done in the state at the present day is carried on.

The provisions of this act are, essentially, as follows: A commission of three officers of the Corps of Engineers of the United States Army are appointed by the President, with the advice and consent of the Senate. This Commission is charged with the enforcement of the provisions of the act. The owners and operators of hydraulic mines are required by law to comply strictly with the requirements of this Commission. An extreme penalty of $5000 fine and one year's imprisonment is provided for violation of the act.

Requirements of the Law

Hydraulic mining is defined as embracing all mining operations where water is used under pressure through a nozzle against any bank of earth, gravel, or similar material, thus eroding the bank. The law requires that in all cases a license or written permission from the Commission must be obtained before hydraulic mining can be legally carried on. Licenses are revocable by

the Commission, and will not be given unless their requirements as to restraining barriers or dams are complied with; and unless these dams are properly maintained, and all information asked for by the Commission is at all times forthcoming, licenses may be revoked arbitrarily by the Commission.

Licenses Under the Caminetti Act

Licenses are not transferable and are valid only for the operations of the special individual, company, and property named in the license. An application for license must be advertised in the newspapers to allow any protests to be filed with the Commission. As soon as practicable after advertising an application, the sites proposed for restraining works are visited, and if found satisfactory by the Commission, authority is given for construction of the barrier or dam, together with specifications and instructions for the work. Any variation in location or change in character of work from that specified by the Commission may cause rejection of the dam. If the work, after inspection, is found satisfactory by the Commission, a revocable license to mine is issued. Until a license has been issued, it is illegal to mine. When mining has been begun, a report every month must be submitted in regular form to the Commission. In case of any accident to the barrier or dam, mining must cease at once and the Commission be promptly notified.

When a dam becomes full of débris, mining must cease until more impounding capacity is provided, either by raising the dam or the construction of new dams. In either case, the permission of the Commission must be obtained, and the work when completed must be inspected and approved by the Commission before work can be resumed. Dams must be kept water-tight and a pool at least two feet deep must be maintained as a settling basin while mining is in progress. Leaks must be promptly checked. Names of mines cannot be changed without due notice to the Commission.

While the above is not the wording of the Caminetti act, which allowed a certain amount of latitude to the Commission, it is in effect an abstract of the conditions necessary for the present-day hydraulic miner, in any of the drainage areas affected, to observe in order to keep within the requirements of the law. It will be observed that the power of the Commission is arbitrary. This is, of course, necessary for the efficiency of the act; but it seems a necessary corollary that the men to whom this arbitrary power is entrusted should be thoroughly familiar with the conditions governing the work which they control.

The area embraced under the provisions of the Caminetti act includes all of the country drained by the Sacramento and San Joaquin rivers and their tributaries. In the northern portion of the state, tributary to the Klamath and Trinity rivers, hydraulic mining is carried on unrestricted, owing to the extreme grade of the rivers and the comparatively small area of valley land along their banks.

At the time of the passage of the Caminetti act there was great jubilation in the eastern mountain counties of the state. Anvils were fired, celebrations organized, and the general idea among the miners was that their ancient prosperity and flourishing condition would be in a measure restored. It was, of course, not expected that mining could be conducted on the same scale as before restrictive measures were adopted; but it was hoped that at least two or three millions a year would in a short while be added to the then dwindling gold production of the state. In the course of a much longer period of time, it was expected that the five to ten thousand millions of dollars still locked up in the Sierras would be added to the wealth of the nation. Another cause for congratulation was that the conditions governing the passage of the act showed that the miners and farmers of the state could act harmoniously and co-operate for the general good of all. As the act was passed for the purpose of reviving the mining industry, it was rightly expected that the débris Commission would not assume an attitude that was either hostile or suspicious of the good faith of the miners.

For a time this seemed to be the case. The then members of the débris Commission seemed to bend every effort to the serving of the best interests of the state. While friendly toward the mining interests, there was still no partiality shown at any point where their interests seemed prejudicial to the good of the commonwealth. With this attitude, the miners were well content, and a certain amount of work was resumed. Restraining barriers were built in conformance with the act, and the sound of the bumping boulder was again heard in the sluice-boxes and ravines of the Sierras.

But not for very long. Changes came in the débris Commission, as was natural in a body composed of army officers, in accordance with the exigencies of the service. New men came in, unfamiliar with the requirements of the mining industry and inclined to regard it as somewhat of a trespasser.

The System of Graft

In addition, the Anti-Débris Association, like many another body originally organized for a worthy purpose, when its purpose was accomplished, speedily degenerated. The employment of scouts, or 'spies' as the miners were disposed to call them, was perhaps the first branch of the activities of the Association to show decadence. Petty graft crept in, and men who were disposed to pay for the privilege of working unrestrained, especially if the property in question were out of the way and inaccessible to the officers of the débris Commission, found out that it was very easy to avoid complaints. On the other hand, men who operated in good faith under the law, if they did not pay tribute to certain individuals, found themselves subjected to continual annoyance and complaint.

This does not in any way reflect on the membership of the débris Commission. Consisting as it does of officers of the United States Army, they are above sus-

picion of connivance with a few petty grafters. The chief trouble with the Commission, as at present constituted, is this: In the first place, they serve without pay, and while the service is given whole-heartedly, their duties in connection with river and harbor work are so exacting and onerous that they must of necessity work in part on hear-say evidence in deciding where to conduct their investigations. Complaints filed by the Anti-Débris Association being their principal source of information, it follows that the latter body has a certain amount of influence, and its petty influence is embarrassing. Add to this the fact that as soon as a man has served long enough on the débris Commission to gain a practical idea of the work of the miners he is apt to be sent to another part of the country, and a new man has to be broken in.

On the other hand, the California Miners' Association, which for many years was the most powerful backer of the hydraulic miners, has, with the development of the quartz interests, paid less attention to the matter and devoted itself to the thoroughly 'legitimate' forms of mining. So the would-be hydraulic miner is left in the lurch. The attitude of the débris Commission is somewhat like that of the corner policeman watching the small boy near the apple cart. The Anti-Débris Association has already been brought into this paper more than the questionable character of its activities deserve; but it is at the present day more in need of a policeman than the miners. And the Miners' Association is now far from being the powerful organization it once was.

The result of all this is that, instead of the tens of millions which were formerly produced annually, and instead of the millions which should now be produced, the production of hydraulic mines in the Sierras is only hundreds of thousands of dollars.

(To be continued.)

COAL-MINE FATALITIES in the United States in September totaled 195, against 173 in that month of 1913. Nine months of this year record 1778 deaths compared with 1916 last year.

MINERAL EXPORTS from Argentina, South America, during the first half of the current year totaled ₱56,131, a decrease of ₱42,657 compared with that period of last year.

COAL PRODUCTION of the Chinese Engineering & Mining Co. during the week ended October 17 amounted to 55,395 tons.

Darrow Tailing Treatment at Bunker Hill

By FRANK LAWRANCE

A clever and most successful slime concentrating plant is in operation on the waste tailing from the concentrating mill at the Bunker Hill mine in Amador county, California. The process used is the outcome of long and persistent experiments made by Wilton E. Darrow, who has finally brought it to a successful issue. The tailing here carries a large proportion of slime in which is fine mineral not caught on the vanners. In the Darrow plant there are four machines treating 200 tons of tailing per day.

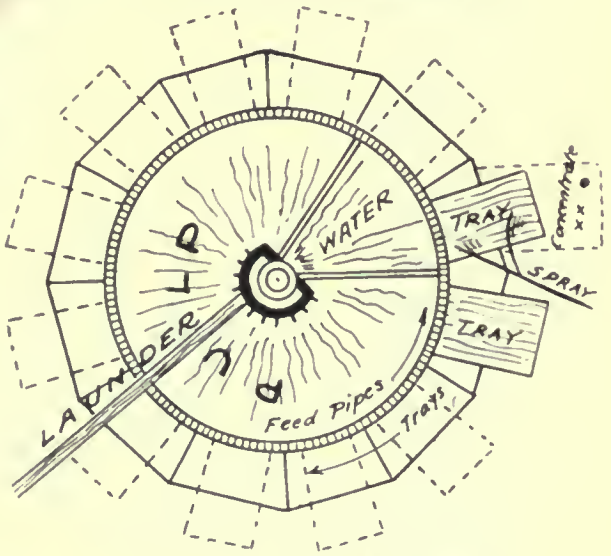
DARROW SLIME TABLE SHOWING CATCHMENT PLATFORM.

DARROW SLIME TABLE WITH THREE TRAYS IN POSITION.

An important feature of the Darrow plant is the elimination of all rubbish such as pulverized wood before the tailing enters the plant. Another feature is a diaphragm-cone classifier which separates the sand from the slime. The sand, containing only 5% that will pass

a 100-mesh screen, is leached in ordinary vats filled by a distributer. The slime is passed over the patent machines, herewith illustrated, after dilution with clear water.

A machine consists of ten tiers of trays each 2 by 4 ft. in area. There are 14 trays in each tier. The feed pipes to each tray are so arranged that each has an equal and even supply of the pulp and the part of the mechanism which supplies the pulp, or in other words carries the feed pipes, revolves in the opposite direction to that which carries the trays, which are on the outside. A small baffle tray at the head end of each big tray distributes the pulp uniformly. Each tray is covered with a piece of common felt roofing paper which has been prepared by painting with B. &. B. paint and sprinkled with sand to form a rough surface like sandpaper.



PLAN VIEW OF DARROW SLIME TABLE.

A plan view of the machine shows a circular table with a slight fall toward the periphery made of thin cement. This table is stationary. The table has two small ridges which cut off one-sixth of the circle to allow clean water to pass down the feed pipes and wash the loaded trays just prior to their approaching the sweeping water sprays which wash the concentrate completely off into a receptacle below. The pulp flows down the surface of the cement table into the trough around the edge, and the feed pipes are screwed into the trough in such manner as to convey the pulp to the different trays. The sprays, of which there are two to each tier, have a sweeping movement and thoroughly wash off all concentrate remaining on the trays after the water wash. When the concentrate is washed off it flows into a general sump and is pumped up into agitation vats and treated by cyanidation and decantation. An excellent extraction results.

The plant requires only one man to look after it, and he does not need to put in more than four or five hours daily. Mr. Darrow has a new plant erected below the Fremont property and has started to treat the tailing from that mill. When one considers that a profit has been made on the Bunker Hill tailing which averaged about 65c. per ton, it is evident that a considerable field exists for this process.

Mineral Production of New Zealand

The *Mines Statement* of the Department of Mines for 1913, recently to hand, shows the following output:

	1913.		1912.	
	Quantity.	Value.	Quantity.	Value.
Coal used, tons	1,676,256	£ 838,128	1,948,603	£ 974,301
Coal exported, tons	211,749	205,010	229,012	216,170
Coke, tons	28	50	4	7
Gold, ounces	376,161	1,459,499	343,163	1,345,131
Kauri gum, tons	8,780	549,106	7,908	401,305
Silver, ounces	975,616	103,866	801,165	84,739
*Sundry minerals, tons	2,927	31,532	1,729	20,571
Total value		£3,187,191		£3,042,224

*Includes scheelite, 221 tons of concentrate worth £22,933, which is recovered from gold quartz mines in the provinces of Otago and Marlborough.

Lode mines produced 464,508 tons of ore yielding £1,071,813, and £287,088 in dividends. Hydraulicking recovered £295,704, and dredges £195,848. There were 74 boats working at the end of 1913, against 87 in 1912 and 201 in 1902. Dividends last year amounted to £18,750.

Eight companies are drilling for oil in the provinces of Taranaki, Wellington, and Hawke's Bay. One concern drilled a well which gave 1000 bbl. in the first two months of 1914. The yield of oil in any of the districts, although of excellent quality, has not been found in commercial quantities. Regulations are being prepared to control drilling and water. Coal decreased 289,610 tons, due to the strike throughout the Dominion. The state collieries produced 196,284 tons. There were 9191 men employed in all operations, the fatal accident rate being 1.74 per 1000.

The total mineral production to date is as follows:

Metal or mineral.	Quantity.	Value.
Antimony ore, tons	3,768	£ 54,941
Coal used, tons	33,812,787	16,814,583
Coal exported, tons	3,536,032	3,254,932
Coke, tons	16,491	24,975
Chrome ore, tons	5,869	38,002
Copper ore, tons	1,495	19,198
Gold, ounces	20,884,312	82,058,543
Kauri gum, tons	330,775	16,759,563
Hematite ore, tons	76	444
Manganese ore, tons	19,364	61,905
Shale, tons	14,423	7,215
Silver, ounces	17,783,621	1,938,714
Sundry ores and minerals, tons	41,442	313,597
Total tons and total value	37,782,522	£121,316,612

SOAPSTONE of commercial grade is reported to occur at various points in southern California, and Los Angeles men are preparing to place it on the market.

THE SHAMVA MINE, Rhodesia, produced $150,000 from 48,489 tons of ore in October. Working costs totaled $1.82 per ton, and the estimate of profit $62,000.

The Cyanide Situation

At a recent meeting of the New York section of the Mining and Metallurgical Society, Mr. Ruhl, of the Roessler & Hasslacher Chemical Co., discussed the beginnings of the American cyanide industry as below:

I really did not expect to speak tonight, and have not prepared an address, therefore can only make a few general remarks on the present cyanide situation; all well known history. Our firm began the manufacture of cyanide in this country in 1890, at Perth Amboy, New Jersey, making the first potassium cyanide of 98 to 99% guaranteed purity, by the old method from potassium ferro-cyanide, using both domestic and foreign raw materials, the latter permitting us to export cyanide made in the United States to Mexico and other Central American countries.

It was seven years before we sold the first carload at 45c. per lb., a most memorable event, although we were told, after the success of the cyanide process in the Transvaal was assured, that cyanide would be wanted here also, by the carload, every hour of the day. The first carload was not sold for gold extraction, but for the fumigation of orange trees, the only recognized remedy against the San Jose pest.

Among our first customers were the Mercur gold mines at Mercur, Utah, and the Brodie cyanide plant at Cripple Creek, Colorado, where I first met your secretary, Mr. Ingalls. J. R. Delamar placed the first carload order for the Nevada Gold Mines, which he had just acquired, after his failure with the Rothwell chlorination process. He only then came to the conclusion that cyanide in its concentrated form was by far a better material to transport than chloride of lime, in large, bulky casks, as the contents of these casks of his first supply were strewn all along the 175 miles from the Milford railroad station to his mine at Pioche, Nevada.

Delamar started with 6 to 8 lb. of cyanide for each ton of ore, the value of the ore at that time being $60 in silver and $15 in gold per ton. As he was anxious to recover the precious metal, he did not mind how much cyanide was used so long as he could secure big results, but it also did not take him long to discover that he was wasting cyanide. The price at which we sold him the first 100 tons was 32½c. per lb., f.o.b. New York. We tested the feed and tailing of the Nevada Gold Mines and advised the neutralization of the ore with lime or caustic soda before cyaniding, which would cut down the consumption of cyanide to 4 lb. per ton of ore. Several years later Delamar's manager, Hartwig A. Cohen, openly boasted of having reduced the consumption of cyanide to 1 lb. per ton of ore, but failed to mention that the refractory ores had fallen in value to $10 per ton.

With the enactment of the Dingley tariff act of 1897, reducing the rate of duty from 25 to 12½% *ad valorem*, we were compelled to cease the manufacture of potassium cyanide. For several years, during the period of the Transvaal war, we resorted to the importation of cyanide. In 1902 we took up the manufacture of sodium cyanide, producing it synthetically, according to an invention of an American chemist, Hamilton Y. Castner. It took fully ten years to reach the high standard of sodium cyanide which we are now producing, equivalent to 128 to 130% potassium cyanide, now universally recognized as the only proper material for electroplating, fumigation, and gold extraction purposes.

Unfortunately for the United States' mining industry and ourselves, after the enactment of the Wilson tariff act of 1913, putting cyanide on the free list, the output of our cyanide factory at Perth Amboy, New Jersey, was not equal to the growing needs of this country; thus it was necessary to import cyanide to meet the increasing requirements of the United States.

At the outbreak of the present unexpected European war, we immediately proceeded to rehabilitate our factory at Perth Amboy, by obtaining additional and sufficient supplies of raw materials so as to operate our works on a much larger scale than heretofore, and thus meet the extraordinary conditions. In addition to this, arrangements have now been made to procure a 1000-ton shipment of cyanide from Germany, which is to come forward on an American ship, and this will also relieve the situation in Mexico, as all the cyanide we intend to import is to provide for Mexican consumption.

If, in common with all other countries, the United States were on a free-trade basis, no protection would be necessary; but with a protective tariff on some things and cyanide on the free list, we are handicapped in the cost of production by reason of the higher cost of raw material, labor, land, equipment, and capital investment compared with European conditions. The total annual consumption of cyanide in the United States is about 2000 tons, and in Mexico 5000 tons. With the enlargement of our Perth Amboy plant, which is now almost ready to begin operation, we shall be able to supply the whole consumption of the United States, but must continue to rely on importations to supply the Mexican demand. Under the Dingley tariff of 12½% *ad valorem*, an amount of protection with which we were quite satisfied, we were able at all times to supply the whole American demand. The raw materials we consume are sodium, ammonia, and carbon.

ALL MINING OPERATIONS, railway construction, and other work on the uplands are at a standstill in Bolivia as a result of the financial crisis precipitated by the European war, according to W. Andrews and his son, mining men who recently returned to Lima, Peru. Patiño's tin mines have closed down, the Pulatayo silver mine has let its 2000 employees go, and every other important corporation in the republic has reduced its force. The Ineaoro gold mine, in which Horace G. Knowles is interested, is practically the only exception. It is understood that the automobile service between Potosi and Sucre has now been established.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Uwarra Mill

The Editor:

Sir—In connection with Mr. Barbour's description of the cyanide mill of the Uwarra Mining Co.,* the following operating data of the mill he describes will be of interest to those who read it. I succeeded Mr. Barbour here in May and the following would only apply from that time to the present. At the time he wrote, the flowsheet was as below, the figures being reproduced from his article. Radical changes were made in this flowsheet of the mill by the elimination of the second set of rolls, all the mechanically operated agitators, and numerous minor power consuming parts of the original equipment. At the present time the ore as mined is relieved of 31% of barren slate at the surface before treatment. Heretofore this amount was considerably less. This has naturally resulted in changing the character of the ore treated, by removing a greater amount of slate which is tough, of larger size, and more resistant to grinding than the gold-bearing fractured quartz and accompanying calcite. An average screen analysis of the feed to the first set of rolls as delivered by the jaw-crusher is given below:

Mesh.	Per cent.
On 1½-in.	7.1
On 1-in.	17.8
Through ¾-in.	75.1

The product from the rolls is elevated to a trommel with half-inch screen from which the undersize goes directly to the 20 by 5-ft. tube-mill after hydraulic classification. With the coarser feed, the tube-mill satisfactorily produced a pulp 95% of which passed a 200-mesh screen. At the present time, after provision had been made for the prevention of settling, the tube-mill delivers a coarser product, as it was found that the same extraction could be obtained on a product between 150 and 100 mesh.

Cyaniding these ores presents but few chemical difficulties. The gold is free, in a clean gangue, and contains but 3% of non-auriferous pyrite in the slate adjoining the vein. The great difficulty experienced in the plant has been the high settling rate of the pulp. I am at a loss to understand the poor performance of the mechanical agitators in the plant. I gather that they choked soon after the plant was started, as about 80% of the tank capacity was occupied by settled pulp when I first saw them. It is evident that the plant has operated since it started with but a fraction of the agitator capacity for which it was designed. The inferences that were drawn from this were that little if any agitation was necessary for an ore of this character. In the pulp storage tank that supplied the Kelly filter, no provision was made to keep the pulp in suspension, and settling resulted. This has been remedied by compressed air. Besides keeping the pulp in suspension, the tank now acts as an agitator during the shift the filter-press is not working. To eliminate the consumption of power, oil, attention, and cause of delay in operating, the three mechanical agitators were thrown out, one of which was

dismantled and converted into an air agitator. This was accomplished while the plant was in operation, and during this time the pulp was sent from the Dorr settler directly to the filter storage tank, where it received some agitation before filtering. There was no perceptible increase in the value of the tailing discharged by the filter during this time. At the present time, the pulp from the Dorr is discharged into the converted agitator, where it is air agitated for half an hour. The new agitator has been in operation for two months now and the tank is absolutely free from settled pulp. An arrangement whereby 70% of the contents of the agitator can be siphoned over to the filter storage tank, prevents the necessity of keeping the agitator in operation to prevent settling, over holidays and repair days. The pulp storage tank is emptied through the filter during shut-downs. The filter-leaves are acid treated periodically, one set being in the acid tank while the other is in use. Since the plant was readjusted the filter discharge has consistently averaged less than 30c. per ton, of which about 40% is soluble. The recovery was 93.7% in June and July, and in October it was 94.2% on the basis of smelter receipts from the shipments of precipitate for the three months. In October the plant operated 90.7% of the total available operating time in the month.

The Shriver press for clarifying the gold solution was replaced by automatic decanting devices which allowed settling before going to precipitation, and excelsior was placed in the upper compartments of the zinc-boxes. The gold solution is clear and no difficulty is experienced in precipitating solutions having only 1.2 lb. of cyanide per ton. The precipitate is of high grade and the last shipment averaged $36 per pound.

Since the changes were made the plant has operated smoothly, made a consistent recovery by bullion, increased the grinding capacity, and eliminated the shut-downs caused by overloaded belt-conveyors and getting ore to pass through a $\frac{3}{16}$-in. screen that fed the second set of rolls. The air agitator in conjunction with the agitation in the filter storage tank, hardly seems to be necessary at this time, on the ore at present treated. It takes two hours for the pulp to reach the filter storage tank from the time it strikes the rolls where it comes in contact with solution. The cyanide consumption for October was 0.32 lb. per ton of ore treated. The mill or circulating solution averages from $2 to $3 per ton. It was found that the value of the overflow solution from the Dorr thickener was richer than the solution going to precipitation. This solution which was worth from $6 to $7 per ton was run to precipitation. The precipitation was so regulated that about 40 tons per day goes through the boxes. The capacity of the boxes is in excess of the requirements of the plant, but the surplus compartments are used as excelsior clarifiers.

The net result of the various changes in the plant and the elimination of the second set of rolls and mechanical agitators which included the use of steam for heating the solutions, is reflected in our coal bills to the extent of 6½ tons per day. Coal in the bins costs $4.20 per ton. I am not prepared to state definitely if stamps would have been better than rolls. However, I am inclined to think that if a five-stamp battery had originally been installed, the superfluous idle equipment would have been saved. The saving in power resulting from high elevator-belts, trommels, etc., would have been appreciable. I am convinced that stamps would have increased the capacity of the plant, as on ore of this character, which is fresh and hard, the rolls are of no assistance whatever to the tube-mill in making slime. The quartz is fractured and readily falls to pieces when the rolls take it. I think Dorr's continuous decantation process would have been ideal for the ore and such a plant would have required less power.

ANDREW WALZ.

Candor, North Carolina, November 10, 1914.

Upper Yenesei Valley and Adjacent Mongolia

The Editor:

Sir—In your issue of October 31, appears an article on the 'Upper Yenesei Valley and Adjacent Mongolia.' Having recently returned from an examination of alluvials in this region and having also just completed a description of my trip, the above article is of especial interest to me.

Referring to the Uriankhai, the writer states: "It is hardly known whether this land belongs to Russia or China," and further on he refers to "the nebulous state of the frontier question." The frontier question in this district has now been definitely and finally settled. The accepted border between Mongolia and Southern Siberia is a line roughly parallel to the Tanna-ola range and passing through points 100 to 150 versts south of the centre ridge of this range and thereby placing all the Tanna-ola territory within Siberia. This line had been defined by the Burin treaty between Russia and China, dated August 20, 1727, but it is only recently that Russia has formally laid claim to it. Soyot or Uriankhai camps and villages on the south of Tanna-ola are named in this treaty, and through these the boundary line passes.

The majority of the maps of this region, including the one you publish, are inaccurate. Those showing the boundary, designate it as a line either following the main Tanna-ola ridge or in some cases 100 miles north of this ridge.

North of the boundary line, in Siberian territory, mining titles now possess the same validity as do those in any other part of the Russian Empire. All mining claims in the Uriankhai region come within the jurisdiction of the Minusinsk district mining engineer.

Although a new district, its inaccessibility, together with the fact that all the promising creeks have been already located by the Russians and Siberians, discourages prospectors from the world outside. Mention is made in the article of "lack of water," also "The

hydraulic method is impracticable in the district, for lack of water, the absence of suitable places for installing a system of hydraulic washing, and other mechanical difficulties." As a matter of fact, I found conditions for hydraulicking excellent, and my clients, following my suggestions, are, next year, equipping one of the creeks with a hydraulic plant. The country I visited is well watered and from 1000 to 2000 miner's inches of water under 800 ft. head can be had from two creeks by constructing in each a ditch six miles long. Next year I hope to be able to publish a detailed description of some of the properties in this interesting district. The dredge referred to on the Saphyanoff property is a 7½-cu. ft. bucket, open-connected, Russian built dredge. It cost in Petrograd R.100,000, while R.100,000 additional was spent in freight and erection. The gravel is about 10 ft. deep, of which half is overburden. Bedrock is very hard. The dredge was expected to dig at the rate of 2500 cu. yd. per day, but in actual operation it is only digging 800 to 900. During the early part of this summer the dredge was running at a loss; its daily clean-ups amounting to only 20 to 40 zol. of gold ($48 to $96). Later in the season, however, it yielded 2 lb. of gold per day ($460). It burns wood which must be carried a distance of 5 versts and employs a crew of 40 men.

NEWTON B. KNOX.

London, November 11, 1914.

[We are fortunate in being able to add this to our previous note on this far off but promising country. Visitors to it have been rare and thus Mr. Knox as the engineer last returned is able to make material corrections.—EDITOR.]

Experimental Development of the Hall Process

The Editor:

Sir—Mr. H. F. Wierum deserves the thanks of the smelting fraternity for his very frank and complete article on the Hall process of smoke treatment, published in the *Press* of October 3. Mr. Wierum is right, the impression made on the public, by the repeated shutdowns, and explanations thereof, was that the method was a complete failure, not a simple question of getting the right washer for the sulphur.

I would like to call Mr. Wierum's attention to a possible help in the method, suggested by a series of experiments carried out at Butte, Montana, while I was in charge of the operations of the Montana Ore Purchasing Co.'s smelter. At that time the 'Eldred Process Co.' proposed to save us some 30% of the fuel used in the reverberatory smelting furnaces. We listened and disbelieved, but consented to make experiments at the expense of the Process company. This was done—and the results justified our disbelief, though the method is of interest, and of possible application to the smoke problem, I think.

Eldred's method was to regulate the combustion of the fuel by the introduction of spent gases, carrying little oxygen, taken from the furnace flues, and forced under the grate of the fire box by means of large fans. It was possible by this means to delay the combustion of the coal to a point where the greatest heat was at almost any desired position in the length of the furnace, or to produce a really reducing flame at will. The mechanics of the method are simple, providing only that the gases are not so hot as to melt the pipes and fans.

The results did not show a benefit for our furnaces, chiefly because ours was a question of forced operation, a question of how much not how little coal we could burn. The furnaces were the old short type, and we had never any trouble getting the flame of the fire to the chimney; but I believe that with furnaces 90 to 100 ft. long this method would show better results. Its application to the Hall process would seem simple; exhaust the gases from one of the upper roasting hearths and introduce them at such point below, as would seem best both to retard the combustion and exclude the outer air. An apparently simple combination of pipes and valves might be rigged, which would permit of the taking of the gases from any hearth and introduction into any other.

I ought, in justice to the Eldred method, to say, that it has been very successful in lime burning, and also in the long cement kilns where economy of fuel is important, and regulation of temperature a necessity.

JAMES W. NEILL.

Pasadena, California, November 30.

Dredging and Hydraulicking in Victoria

*At the end of 1913 there were 119 properties covering an area of 12,863 acres being worked in this state of Australia. Fifty-one bucket-dredges handled 14,946,933 cu. yd. of gravel, yielding an average of 6.4c. per yard, also a total of 7.25 tons of tin worth $4000. One boat recovered only 3.2c. per yard. There were 694 men employed. Each plant yielded 27.4 oz. per week, and the total cost of operation was 19.7 oz. gold. The greatest amount treated by one boat was about 14,000 cu. yd. per week. The output was a decrease compared with the previous year. Dividends totaled $173,000. Twenty-six pump-sluicing plants moved 1,191,817 cu. yd., yielding 14.4c. per yard, also 25 tons of tin, valued at $14,500. There were 325 men employed. Average weekly yield of gold per plant was 31.9 oz., and expenses 21 oz. One plant treated up to 9000 cu. yd. per week. The sum of $4900 was paid in dividends. Fifteen jet elevators treated 567,273 cu. yd. for 12.4c. per yard. They employed 80 men. Five gravitation sluicing plants recovered 12.7c. per yard from 90,562 cu. yd., and employed 31 men. A total of 16,706,023 cu. yd. was treated by all plants in 1913.

*Abstract from report of the engineer, D. B. Sellars, for the state government.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Silver worth $185,270 was produced from the Kongsberg mines of Norway in 1912-13.

Consumption of potassium and sodium cyanide combined, in the mills of South Dakota in 1913, was 502,688 lb. in treating 1,855,000 tons of crude ore and amalgamating mill tailing. This is equivalent to 0.37 lb. per ton of material milled.

Amber is a light yellow, fossilized, vegetable resin, mostly mined from deposits near Danzig and Königsberg in East Prussia. The output in 1913 was 427 metric tons. Some amber is also found on the Baltic coast near Libau in Russia.

Amalgamation mills of South Dakota in 1913 used 12,150 lb. of quicksilver. There was 1,540,961 tons of ore treated by this process, yielding 224,648 oz. gold. One ounce was used in recovering each 1.55 oz. gold; one pound was consumed for each 127 tons of ore milled.

Iron ore amounting to nearly 1,000,000 tons was mined from the Sydvaranger property, county of Finmarken, Norway, in 1913. Seventy per cent of the product went to Germany. There were 1300 employees, who received $536,000 in wages, or $412 per man per year.

Oil is recovered from whales in large quantities, and in 1913 Norwegian companies operating in all parts of the world had a total production of 595,000 bbl., worth, with by-products, $9,648,000. Prices for whale oil, according to quality, varied from $5.11 per 100 lb. for No. 0 to $4.13 for No. 4.

Products valued at $40,200,000,000 per year are made by all industries in the United States under the following heads: factories, $27,000,000,000; farms, $9,750,000,000; forests, $1,250,000,000; and mines, $2,200,000,000. The proportions of the world's mineral output supplied by this country are as follows: pig iron, 43%; oil, 65%; copper, 55%; zinc, 34%; lead, 31%; and coal, 40 per cent.

Contraband of war is a subject not understood by many, and the list of articles affected is at present being continually added to. Some of the 'absolute' contraband are as follows, as declared by England: Aluminum, armor plate, copper (unwrought), chrome ore, and ferro-chrome, ferro-silicon, iron, iron ore (hematite), iron pyrite, lead in all forms, mineral oils and motor spirit (except lubricating oils), nickel and nickel ore, powder and explosives prepared for war, and sulphuric acid. 'Conditional' contraband includes fuel other than mineral oils, glycerin, gold coin or bullion, powder not prepared for war, silver coin or bullion, and sulphur.

Anomalies in trade are difficult to understand sometimes. On the island of Hawaii, of the Hawaiian group, a lumber company is cutting a small quantity of *ohia*, a dense hardwood, railroad ties from which are sent to the United States for the Santa Fe line, while California redwood ties are sent to the island for the Hilo line, over which the *ohia* ties are hauled for shipment to California. Both the white ant and carpenter bee damage lumber on the islands.

In board measure a foot means one foot both in length and breadth, and one inch thick; consequently to obtain the number of feet board measure (b.m.), of a board, or a square timber, multiply the length in feet by the breadth in feet by the thickness in inches. To find the volume of round timber in cubic feet when all dimensions are in feet, multiply the length by one-quarter of the product of the mean girth and diameter, and the product will be the measurement required. To find the volume of square timber when all dimensions are in feet, multiply together the length, breadth, and depth, and the product will be the volume in cubic feet.

The Welland canal is one of the most important waterways in Canada, being a channel between Lake Erie and Lake Ontario. It has 25 locks, each 270 ft. long, with 14 ft. of water on the sills. This canal has outlived its usefulness, and the new Welland ship canal is now being constructed, 2000 men being employed. It will be 25 miles long, 200 to 310 ft. wide, 30 ft. deep, and will have seven locks each 800 ft. long. The total lift will be 325.5 ft. Panama and Sault Ste. Marie Canals' lock gates miter, but these will be of the single-leaf type, being 3 ft. longer than the width of the canal, making it slant into the opposite wall. The waterway is to be finished in 1918, at a cost of $50,000,000.

The efficiency of a steam power plant when operating in parallel with a hydro-electric system is discussed by Edwin A. Rogers in the *Pacific Service Magazine* for November. In a modern boiler plant heat losses are 21%, made up by 3% for loss of steam for atomizing, 15% stack losses, and 3% by radiation. Another 4% of heat is lost in pumps and auxiliary plant, and 1% in radiation and friction in a turbine. Of 74% of the original heat available at the turbine, 60% is rejected to the condenser, leaving only 14% efficiency from the engine in the form of electric energy. In other words, starting at the oil tank with $1 worth of heat, the switchboard yields only 14 cents worth of work.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

GERMAN INTERESTS IN ENGLISH COALFIELDS, AND THE SUPPOSED PURPOSE OF THESE INTERESTS EXPLODED.

Matters connected with the war continue to absorb a large part of the attention of mining men, and I cannot do better than to continue to recount in these columns some of the antagonisms real or assumed between English and German patriotisms. Some notes on the so-called invasion of English coalfields by German capital should be of interest. In south Wales, in Yorkshire, and in Kent are to be found examples of Germany having acquired a foothold in the way of ownership of one of Britain's most cherished natural resources. English people have not generally objected to the sale of coal in the ordinary way of business to German mercantile firms for delivery to Germany, or to other parts of the world, though among the perfervid the propaganda has been popular for the absolute prohibition of coal exports in any shape or form. This refers of course to pre-war times. But it has been somewhat bitter to know that English coal lands should be sold to Germans. That such a thing should be possible hurt our proper pride. Consequently when J. C. A. Henderson, one of the lesser Rand magnates, connected with the East Rand Proprietary and Henderson's Transvaal Estates, acted as intermediary in 1905 in the sale of the Whitworth estate at Fforchdwm in Glamorganshire, south Wales, to Herr de Freitas, of Hamburg, there was a loud howl of execration throughout the country. Those in the know in south Wales, however, did not feel much concerned, as the colliery had not up to that time proved workable, owing to the tremendous inflow of water from the overlying strata; and in any case there were serious doubts as to the alleged existence below the workings of the seam of high-class smokeless coal that is the source of so much wealth to coal estates several miles east. Sinking to the expected horizon of this seam was undertaken by the de Freitas company, but the water difficulty was never overcome, and two years ago the two shafts were abandoned at 1450 and 1100 ft. respectively. The unfortunate part was that English investors were induced to subscribe some of the capital. Massive concrete foundations had been prepared for the power house, and during the past month or two these have provided the inevitable scare, a sensitive public being easily induced to believe that they were to be used as emplacements for guns. Seeing that the pit is 10 miles from Swansea, and 5 from Neath and Port Talbot, inhabitants of these towns began to fear. The pit is also near the main line of the Great Western railway from London through south Wales to Fishguard, and is within striking distance of the collieries in the Rhondda valley. The only weak point about this scare was the fact that no guns were erected by the alien enemy or were likely to be.

The next wave of indignation occurred three years ago, when German money and German sinking and boring methods were used in north Kent between Canterbury and Margate. The company formed to work the estate was called the Anglo-Westphalian Kent Coalfield, Limited, and the mineral rights were obtained from the owners, the ecclesiastical commissioners, that is to say, the government department handling the property and revenues of the Church of England. Among the shareholders are the Allgemeine Tiefbohr und Schachtbau Aktiengesellschaft and the Kolonial Handelsbank, while on the list of directors are such names as Peritz and Seitz. Germany is by no means in control, however, for some of the big colliery owners in south Wales have important interests. Nevertheless the boring at Chislet was held by the military authorities to be on a site suitable for a gun that would command the entrance of Thames and Medway rivers, and within striking distance of warships passing to and from Sheerness and Chatham. So the site has undergone inspection, and will no doubt not be forgotten by the military authorities.

At the other end of the Kent coalfield is the old original sinking on the shore under Shakespeare cliff, two miles west of Dover. Here the Channel tunnel workings were commenced in 1880 by the South Eastern railway. After the suppression of the tunnel scheme by Parliament, the railway company adopted W. Boyd Dawkins' suggestion to use the sinking for the purpose of testing Godwin-Austen's theory of the existence of a coal-basin under the Mesozoic rocks of Kent. In 1891 borings below the shaft proved the theory to be correct. But as a commercial project the venture has been a failure, and many have been the vicissitudes of the company having the matter in hand. It happens that at the last reconstruction, a London financial house of semi-German constitution, L. Ehrlich & Co., undertook to provide funds. This firm did much good work in early days in financing the Spassky copper mine in Siberia, and is well known in South Africa. Three of the partners are of German or Austrian birth, though naturalized here for business purposes. The fourth partner and the consulting engineer are, on the other hand, strongly British. At the outbreak of war the connection of this firm with the Shakespeare colliery induced 'scaremongers' to write to *The Times* alleging that the foreigners in control had schemes on hand for undermining the Dover fortresses. Not only was this to be done from the colliery itself, but, ac-

MAP OF THE KENT COAL AREAS, SOUTHEAST ENGLAND.

cording to these 'know-alls,' two bores had been sunk, one two miles northeast of Dover castle, and another two miles to the northwest. No doubt this would be a glorious scheme for the destruction of the magnificent defences of Dover. But it is only German spies or lunatics that would suppose the English military authorities at Dover not to be cognizant of what is going on in their immediate vicinity. The scaremongers' insinuations are, of course, absurd.

The German invasion of the South Yorkshire coalfield is a much more serious affair than those quoted above. A year ago Hugo Stinnes, one of the large German coal merchants, intimately connected with the government of his country, and also with its coal enterprises in Turkey, bought the Harworth estate on the borders of Yorkshire and Nottinghamshire, a few miles east of Sheffield. Mr. Stinnes has worked through a limited company registered in England as a coal buyer, and has offices in practically all the coal ports, so that he has figured largely in the export coal trade. The mineral rights in the Harworth estate were sold to him through Arnold Lupton, who was formerly professor of mining in the University of Leeds, and more recently an eccentric member of Parliament. The purchase was completed about a year ago and sinking was commenced in March last. A colony of German workmen was introduced to conduct the sinking. When war was commenced, most of them were interned and operations were suspended. The pits had not reached the seam, which was expected at 2400 ft. The estate is an extensive one, and the coal resources are estimated at 750,000,000 tons. The scale of operations was designed to handle 1,500,000 tons per year. English coal owners are prepared to purchase the property, but terms of payment cannot be considered until after the war. It will be seen from the above records that the Harworth venture was the only purely German enterprise connected with English colliery development, and that no coal has yet been won from collieries partly or wholly under German influence.

In *The Mining Magazine* for November the Kent coalfield is described by E. B. Lichtenberg, from which article this map is reproduced.

NEW YORK

Butte-Duluth Acquired by Hayden, Stone & Co.—Jumbo Extension Rise.—Anyox Smelter.—Copper and Zinc.—Alaska Ebner Mine.

The taking over of the Butte-Duluth copper mine by the Hayden-Stone syndicate is the most interesting of recent events, and this addition to its holdings in the Butte district considerably increases the importance of this group in that district. The Butte-Duluth and the Bullwhacker have been doing a great deal of experimental work in the endeavor to develop their leaching processes to a point where there is a good working profit, but neither of them has so far attained any great degree of success. Following the announcement made some months ago that the Utah Copper was to use a leaching process to treat its oxidized ores, the acquiring of this property, in which the ores are chrysocolla in a silicious gangue, is of a great deal of interest. The price reported to have been paid for the property is $4,500,000; which seems large on the basis of what has so far been done on it, though earlier this year Walter H. Weed reported on the property and seemed quite hopeful of its future.

Jumbo Extension of Goldfield shares, which on December 1 were up around $4 each, sold the next day down to $2.37. The decline is doubtless due to the growing belief that there is little possibility that the mine will eventually produce enough ore to justify the price of about $6,000,000 which the higher quotation placed on it. High-grade ore is always likely to cause excitement in mine shares, but the profit is usually made out of large quantities of lower-grade material. It is sincerely to be hoped that the Jumbo Extension will make good and justify the advance in share quotations which it has made, and has caused the other minor Goldfield issues to advance in sympathy with it. Such an advance would tend to cause a good feeling in the Curb market; but, on the other hand, if it has the same dénouement that the North Star had a short while ago, the effect in a market which is only just beginning to get back to normal in recovering from the effects of the war will be bad indeed.

Reports from the Anyox property of the Granby company state that two furnaces are in operation and that during October 1,794,308 lb. of copper was produced, at a cost of 8c. per pound. The smelter is now making a satisfactory showing, and it is probably not generally known that this is due to George A. Guess, who is professor of metallurgy at the University of Toronto. The ore at the Anyox is so high in sulphur that it was expected that the ore could be smelted without other fuel than the sulphur. When the furnaces were blown in, however, they failed to work satisfactorily, and Mr. Guess was called upon to diagnose the trouble and point out the remedy. He found that the design and operation of the furnaces were such that it was hard to get enough air through them for the proper conduct of operations, and by changing the character of the charge and the design of the furnace slightly, he was able to remedy this difficulty, with the good results that are shown. The incident is worth repeating, since the general public belief is that college professors are more likely to get plants into trouble than to be able to remedy the mistakes of operating men.

There was not much change in the copper situation last week, except a stiffening of the price and a probable further decrease of accumulated stocks, which can only be estimated, since the Producers' Association has not given out its figures for the past three months and has no immediate intention of doing so. Several Italian steamship lines, notably the Navigazione Generale Italiana, Italia Societa di Navigazione, and La Veloce Navigazione Italiana, have announced that they will accept shipments of copper, but it is still impossible to secure insurance unless the shipper waives his claim to loss through detention by England. At the steamship *Ran*, bound for Sweden with a small amount of copper on board, has been taken into Liverpool, and the *Sigrun*, bound for Malmoe, was taken into Newport, a few days earlier, it seems rather probable that shipments will be detained, as Sweden is one of the countries which has given guarantees against re-export with which Great Britain has expressed itself as satisfied. Shipments from New York during the first week of November are reported as follows: Havre, 3,138,406 lb.; Gothenberg, 2,800,172; Liverpool, 2,611,605; Genoa, 672,318; Christianla, 448,472; Lisbon, 336,135; and Glasgow, 60,730 lb. Copper exports in October, according to figures just given out by the Custom House, amounted to 55,980,643 lb. of pigs, ingots, and bars, 2,683,994 lb. rods and wire, 174,681 lb. plates and sheets, and 4577 lb. of other forms. Italy ranked first in the list of countries to which the metal was exported, with total takings of 21,270,187 lb. England took 17,940,371 lb., and France 5,351,864 lb. The total value of all forms of the metal exported was $7,213,700.

The high record in the exports of zinc made in the last three months is reflected in the strong price of spelter. The exports in September alone, 38,090,144 lb., exceeded the total of any previous year. Most of this, or 28,000,000 lb., was sent to England, 3,000,000 lb. each to Scotland and France, and 333,000 lb. each to Denmark and Italy, while 1,250,000 lb. went to British Africa and 250,000 lb. to Australia. Exportation of 65,504,574 lb. of zinc for the three months ended with October represents about 10% of the annual domestic product. During the first week of November 672,885 lb. was shipped to Archangel, 224,071 to Genoa, 1,120,126 to Havre, 1,030,568 to Liverpool, and 224,069 lb. to Sydney.

The Consolidated California-Nevada Co. is to be organized in Delaware with $5,000,000 capital, in $5 shares, to hold the assets of the Alaska-Ebner Gold Mines Co., which was sold at a foreclosure sale recently for $225,000. The assets do not include the 100,000 shares of Ebner Gold Mines Co. which has been optioned to the United States Smelting, Refining & Mining Co. A. W. Middleton has proposed to the shareholders of the defunct Alaska-Ebner Gold Mines Co. that they pay a 50c. assessment and receive one share in the new Company for each share of the old. Most of the properties, outside the Ebner mine, which is not included in the assets of the new Company, do not appear to be of much promise.

AUSTIN, TEXAS

DEPOSITS OF MINERALS IN THE STATE READY FOR DEVELOPMENT AND EXTRACTION.

Commercial deposits of many minerals which are obtained from Europe are known to exist in this state, and William B. Phillips, director of the bureau of economic geology and technology at the University of Texas at Austin, has received numbers of inquiries regarding certain mineral products which the bureau has been importing. He states that in view of the war, and that these deposits occur, and there is a demand for these products, the time is opportune to develop such resources of the state.

Two large deposits of celestite (strontium sulphate) are found near Austin, while there is one in Lampasas county and another near Strickling, Burnet county.

An asphaltic limestone area near Burnet has been purchased by New York people, who intend extracting ichthyol from it, a product obtained exclusively from Austria. This mineral

SULPHUR IN CULBERSON COUNTY, TEXAS.

deposit is also valuable as road-making material and may be mined by steam-shovel methods.——At Pilot Knob, near Austin, is a large deposit of basalt, excellent for paving and road construction.——The alleged large deposit of nitrate of potash in Brewster county does not exist, there being only small quantities of it.——Not much encouragement is offered for the development of radium-bearing ores of the state.——There are some deposits of asbestos and graphite in Llano and Burnet counties, but are not exploited.

In Culberson county, in the western part of the state, 15 miles from a railway, there is a fine deposit of sulphur, estimated to contain 300,000 tons within 30 ft. of the surface. One test-pit was still in sulphur at 41 ft. A small refining plant was operated for a short time several years ago. The sulphur could be extracted at less cost than that underground at Freeport, Texas.—— Iron ore exists in Mason county, in close railroad communication with the Thurber coalfields.

The University of Texas has a splendid collection of specimens of all the state's minerals, but which is not in a place easily found by inhabitants of or visitors to Austin.

WASHINGTON, D. C.

MINING BUSINESS PROBABLE IN CONGRESS: CODIFYING MINING LAWS. SAFETY IN MINING, AND CONSERVATION.

To what extent there will be mining legislation in the short session of Congress, will depend on the excitement that may occur during the session. If there is to be lots of it, there is little chance for legislation worth while, as there will be so little time. If the session is to be humdrum, much of it may go through. The chief measure before Congress of interest to mining men, apart from the leasing bill, is the bill to create a commission to codify the mining laws of the country. It has already passed the Senate, and awaits action in the House, where a bill to create a commission is on the calendar, but different from the Senate bill. It is believed that this bill will have no mean chance of passage. It has heretofore been chiefly fought by the leaders, because it carried an appropriation of $25,000 to defray the expenses of the commission; but it is not thought the paltry sum will stand in the way in the short session, when the statesmen are not likely to be bothered by thoughts of economy; there is no immediate election at hand. What is of graver moment is the fear and opposition in mining circles that the commission would in its codification change the mining laws appertaining to apex mining, which many desire not disturbed. It develops that there is a considerable sentiment, certainly in Congress, for a change in the law of extralateral rights. M. D. Foster, of Illinois, the chairman of the House Committee on Mines and Mining, permits himself to be quoted as saying that the apex mining laws ought to be changed. That the codification commission is expected to do, in his opinion. Of course, whether or not the commission does so will have the force only of a recommendation to Congress, as the codification would have to be ratified by both houses of Congress.

Mr. Foster is also anxious to have action by Congress on his bill for additional safety in mining practice in rescue stations, but apparently this bill will have to take its chances on the state of the calendar of the House on Wednesdays. There will be but few Wednesdays in the session, and the mines and mining committee is fairly down on the list in the call of committees. The prospects are not good. In the House there is a special rule for the calling up and consideration of the radium bill, a conservation measure, but should this even pass in the House, its prospects in the Senate look poor. The Senate has so far presented insurmountable obstacles to the Walsh bill to the foregoing effect.

The Senate presents an interesting situation on the bills there in other respects that interest mining men. There is the leasing provision in the bill sent to the Senate after having passed the House, for the encouragement of the exploration of coal mining lands on the public domain, etc. The Administration is very fond of this bill and all the conservation proposals. It has set its heart on them, and caused them to be passed by the House. There is energetic opposition to them in the Senate by powerful Senators, and especially those in the West who are not keen on conservation principles, and they seem in control of the situation. It would seem that no legislation would eventuate on the bills except through compromise. Both sides are obstinate, but the Administration is a great force, and the Interior Department, through Secretary Lane, is most enthusiastic to see the bills through. By threatening an extra session to consider the conservation bills should Congress in the short session fail to pass them, the President could hold quite a club over Congress, so to speak, as it does not, by a good deal, want to be called into extra session.

JOPLIN, MISSOURI

Activities of the Picher Lead, Commerce, and Cornfield Companies at Miami, Oklahoma.—Hopaloosa Prospecting Co. at Joplin.—Mining on an Island.

The Picher Lead Co., operating a sublimed white lead plant at Joplin, has gone into the mining and leasing business on an extensive scale, having acquired more than 1000 acres of land, mostly Indian property, lying on the high prairies north of Miami, Oklahoma. Over 100 drill-holes have been sunk, many of them showing ore. Lessees are starting on tracts of the Picher land, several shafts have been started, and one or two mills are in prospect. This work represents development in an entirely virgin field, which for more than a year past has been prospected extensively. The average depth of the ore is from 250 to 300 ft., and no water is encountered in the shafts that have thus far been sunk until 200-ft. depth is reached. Below this level it becomes necessary to use pumps. The William M. Sheridan Co. (Inc.), of Chicago, has one 40-acre sublease of the Picher land, on which a number of drill-holes show the deep run of ore. A substantial derrick has been erected and a large shaft, 7 by 9 ft. in the clear, has been started, and is now down 40 ft. The Picher company has blocked out an extensive formation of sheet ore at a depth of more than 200 ft., far to the northeast of any present mining development. The Company will probably mine this tract on its own responsibility.

South of the Picher holdings, which reach north into Kansas, the Commerce Mining & Royalty Co., operator of some of the largest mines in the Miami district, has been instrumental in bringing in some good drill-holes in virgin territory. A recent drill-hole went into ore at a depth of 250 ft., continuing down to 275 ft. Little lead ore was met with, the 'dirt' being rich in zinc-blende. Clippings for a distance of 5 ft. showed 43% blende; the average for the entire 20 ft. being better than 15%. The heaviest producer in the Miami district at the present time is the King Jack mine, which until recently was not looked upon as an especially rich property. The Commerce company took over this property after a previous company had given it up. Prospect driving revealed good ore in the upper ground, and new drifts have been driven at a depth of 120 ft. The record day's run consisted of a production of 30,000 lb. blende, 12,000 lb. galena, and 1200 lb. sludge. This production came from 225 cans of ore, the recovery for the day being 14½%. The same Company is sinking a new shaft to a depth of 205 ft. on the Tango lease in the west part of Miami, where previous operations had been in the upper ground.

In the extreme northeast part of the developed portion of the Miami field, the Cornfield Mining Co. has completed the framework of a 250-ton mill, the cost of which, when finished, will be $18,000. This is one of the few entirely new mills of the district. It has a capacity of 250 tons per day, and is equipped with modern devices for complete concentration. ——Some distance to the northwest of this property the Blue Goose Mining Co. is sinking two shafts to a depth of 260 ft. One of the shafts is into ore at 150 feet.

The Hopaloosa Prospecting Co. has been organized with the view of obtaining leases on various tracts of land, prospecting them with drill and either subletting them or operating them on its own responsibility. In the Company are George Gist, Bert McCullough, Bert Pearson, and Ben F. Wurzel, all of Joplin. Leases have been acquired on 20 acres of the Rose land, 10 acres of the Nelson land, 40 acres of the Kincheloe land, and 15 acres of the Wier land, all situated a short distance south of the city limits of Joplin. A prospect drill has been started. On the Boruff land, in this same district, some good shallow lead ore is now being mined.

A shaft has been sunk on an island in the centre of Spring river near the Kansas-Missouri state line, some distance northwest of Joplin, by the Chicago Mining Co., and although the scene of these mining activities is surrounded on all sides by water, there is barely enough water in the drifts to supply the mill, which is situated on the mainland on the Kansas side of the river. An aerial tramway carries the ore from the island shaft to the mill. A. M. Gaines is manager of this property, which was formerly operated by the Lynas Mining Co., previous mining having been done on the mainland. Steady turn-ins of ore are being made from a working depth of 100 feet.

Operators are encouraged by the reported decrease in spelter supplies in this country, the heavy exports to Europe having cut down the surplus tonnage of zinc and having created a better demand for ore, the price of which now ranges from $43 to $46, basis of 60% metallic zinc, a material increase over the offerings of a few weeks ago. At the recent rate of exportation, the entire zinc production of the Missouri-Kansas-Oklahoma district would barely supply enough metal to meet the foreign demand. This condition, coupled with the fact that importations of ore, which usually are heavy, have been reduced to a minimum, would seem to mean that a much stronger zinc market may be anticipated in the near future.

HOUGHTON, MICHIGAN

Taxes.—Osceola, Centennial, Copper Range, Calumet & Hecla, and Mineral Range Companies.—Copper Shipments.

A review of the Houghton County assessments was held in Houghton, December 3, by State Tax Commissioners Kearney and Horton. The equalization review resulted in the reduction of $100,000 from Franklin township. During the hearing the fact was brought out that, through an error of the equalization committee, the Franklin Mining Co. had been assessed too high. When assessments were made earlier in the year, the Company was not operating, but it was assessed as a producing but non-dividend-paying mine, and thus valued $125,000 higher than it should have been. This error, however, could not be rectified in an equalization review.

The Osceola and Centennial mines are now working full time instead of at 75% capacity. Practically all work will be done on contract, and the men have willingly accepted a reduction in wages. Even with the reduction, the present monthly wages will mean more money to the miners than the higher pay at reduced time. This plan will also mean an increased 'rock' tonnage for the companies, and will make it possible to keep the mines operating without a loss.

The Copper Range Consolidated contemplates no change this year. The mines of this Company are now operating 15 days per month.

With the close of navigation on the Great Lakes, the copper country docks are cleared of all copper on hand. The last shipments of the season were made December 1, when two large cargoes left for Buffalo. All available metal was shipped, and the clean-up during the last month has been most unusual. The vessels carried copper that was smelted even on the day of sailing. It is reported that approximately 45,000 tons of copper was shipped by boat during the past season.

The Calumet & Hecla company reports that it is operating at 75% capacity. Wages are 10% and salaries 15% lower than prior to August 1.——Revenue of the Mineral Range Railroad in October was $70,082, with $10,379 net; since July 1 the total was $281,018, an increase of $156,685, with $32,537 net. The railroad is handling a large tonnage of rock from the mines to the mills, there being only about 19 or 20 working days at the mines each month. In November, in 19 days, the line moved 7384 cars containing about 295,360 tons. In normal times the movement is over 10,000 cars per month.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ARIZONA

Gila County

A contract for 112 double-deck tables has been let to the Deister Machine Co. by the Inspiration Consolidated Copper Co. for its new mill at Miami.

Mohave County

It is proposed to form a Chamber of Commerce and Mines at Kingman, and a committee of investigation was appointed at a preliminary meeting of those interested——The Tom Reed mine produced gold worth $116,000 in October, but in November the yield was about $100,000, the normal output.

The Pittsburg mine has been opened to 187 ft. and the workings show about $20 ore throughout.——The Golden Eagle and Silver Bell claims are in the Cedar district and are opening satisfactorily.——Molybdenite-copper ore of the Copper Cañon mine show a good recovery by the Minerals Separation process as tried in San Francisco.

CALIFORNIA

The California State Mining Bureau, San Francisco, has just issued *Bulletin* No. 68, 'Mineral Production for 1913.' While somewhat belated, it is of value, and contains some interesting new features. The publication covers 138 pages, with an Index, and has 20 county maps showing the latest information. Many inquiries having been made regarding mining laws, 30 pages are given to the federal and state statutes governing mining, the California mine bell signals, and forms of location notices. The mineral output of the state last year was valued at $98,644,639, compared with $88,972,385 in 1912. These figures, as far as possible, refer to the value at the property of crude mineral substances. In the total value of mineral products, California leads all states west of the Mississippi river. Every county of the state contains some deposit, and in 1913 56 of the 58 counties reported a commercial output, from Kern with $28,486,193 to Alpine with $541. Dividends amounting to $20,000,000 were paid from the past year's output. The following table shows the yield of mineral substances as compiled from the returns received at the Mining Bureau in answer to inquiries sent to producers.

Substance.	Amount.	Value.
Asbestos, tons	47	$ 1,175
Barytes, tons	1,600	3,680
Bituminous rock, tons	37,541	78,479
Borax, tons	58,051	1,491,530
Brick	358,754,000	2,915,350
Cement, barrels	6,167,806	7,713,021
Chromite, tons	1,180	12,700
Clay, tons	231,179	261,273
Coal, tons	25,198	85,809
Copper, pounds	34,471,118	5,343,023
Feldspar, tons	2,129	7,850
Fuller's earth, tons	460	3,700
Gems	.....	13,740
Gold	.....	20,406,958
Graphite, pounds	2,500	25
Gypsum, tons	47,100	135,050
Infusorial earth, tons	8,645	35,968
Iron ore, tons	2,343	4,485
Lead, pounds	3,640,951	160,202
Lime, barrels	613,444	528,547
Limestone, tons	301,918	$ 274,455
Magnesite, tons	9,632	77,056
Marble, cubic feet	41,654	113,282
Mineral paint, tons	303	1,780
Mineral water, gallons	2,350,792	599,748
Natural gas, cubic feet	14,210,836,000	1,053,292
Petroleum, barrels	94,494,532	48,578,014
Platinum, ounces	368	17,738
Pumice	.....	4,500
Pyrite, tons	79,000	218,537
Quartz rock, tons	4,040	7,756
Quicksilver, flasks	15,661	630,042
Salt, tons	204,407	462,681
Sand, glass, tons	14,578	14,143
Sandstone, cubic feet	62,227	27,870
Silver	.....	32,553
Soapstone, tons	1,350	6,150
Soda, tons	1,861	24,936
*Stone industry	.....	6,168,020
Tungsten ore, tons	7,592	234,673
Zinc, pounds	1,157,947	64,845
Total		$98,644,639

*Including granite, macadam, rubble, paving blocks, sand and gravel.

Of the increase of $9,672,254, oil accounted for $6,649,670; cement, $1,668,363; gold, $693,480; and the stone industry, $691,092. There were a number of fair decreases in various products.

MAP OF CALIFORNIA, SHOWING GOLD DREDGES.

The mine safety work of the California Industrial Accident Commission was started in January of the present year, under a co-operative agreement with the U. S. Bureau of Mines. Under this one of the engineers of the Bureau was assigned to California, half of his expenses being paid by the Commission and half by the Bureau, it being understood that all of his time should be spent in the state.

During the period January 1 to October 31, 1914, 77 mines were visited, and 503 safety suggestions were made. These suggestions affected the safety of approximately 5392 employees (3661 underground and 1731 surface). This first series of inspections was made as rapidly as possible in order that the Commission might have available, at the earliest possible date, first hand information about mining conditions in California. Almost without exception the mine managements expressed their intention of complying with all suggestions that were made, and in most instances expressed their appreciation of the help which was given and their desire to co-operate in every possible way in the 'Safety First' movement.

At the request of the Commission, the Bureau detailed one of its first-aid miners for work in California, with the understanding that this man's salary should be paid by the Bureau and his traveling expenses by the Commission. He started work in June, and up to October 31 had visited 26 mines, and had given 10 hours' first-aid training to each of 256 miners. First-aid clubs have been organized to continue the work at practically all the mines which have been visited. On Labor Day, as has been mentioned in the *Press*, a first-aid contest was held at the miners' picnic grounds between Sutter Creek and Jackson. Three teams entered for the contest and quite a large number of spectators witnessed it. Cash prizes were offered by the Miners' Union and the various mine operators. This meet aroused a great deal of interest in the first-aid work.

Arrangements were made for mine-rescue car No. 5 to visit some of the California mining districts and give training in rescue work, and first-aid-to-the-injured practices. The car visited 10 mines, where it trained 78 men in first-aid and 26 in mine-rescue work. It also visited Stanford and California universities, where it trained 46 mining students in first-aid and 35 in rescue work. To show its hearty co-operation in the safety-first movement, the Southern Pacific Railway Co. furnished free transportation for this car in California.

Amador County

A reinforced-concrete dam, 440 ft. long and 60 ft. high at the centre, has been built across a ravine to impound tailing for the Kennedy company, near Jackson. This was to complete an agreement with farmers along Jackson and Dry creeks, who alleged that their land was being covered by mill residue.——At Plymouth, the Plymouth Consolidated is building a hospital for miners, and it is said that there will be a resident physician.

Eldorado County

A 5-stamp mill is now crushing ore at the Pacific mine, near Placerville. This property is under lease to P. D. Burtt and J. H. Santo, and has not been operated for 8 years.——The Invincible Mines Corporation's properties in the Horseshoe Bar and Volcanoville districts of this and Placer county have been deeded to John A. Britton and others of San Francisco.

Inyo County

The Cerro Gordo mine is described with illustrations in *The Inyo Register*, published at Bishop. During the current year, to October 1, 2779 tons of silver-lead ore has yielded $223,125. Mining is being done to 700 ft., and the ore averages about 80 oz. silver, 20% lead, 4% copper, and $1.60 to $1.80 gold. It also contains 45% silica and 2% zinc, apart from the real zincy ores. The product goes to Midvale, Utah. There are 56 men employed, L. D. Gordon being in charge, with J. C. Climo as superintendent.

Los Angeles County

The Chamber of Mines and Oil of Los Angeles has issued the first number of its *Oil and Mining Bulletin*, under the editorship of J. Nelson Nevius. The *Bulletin* will be published monthly at 15c. per copy or $1.50 per year. The Chamber has been in existence for eight years, and has endeavored to foster the mining industry. This issue contains discussions on proposed oil and gas legislation, the Plymouth mine, Federal Reserve banking system, California Metal Producers' Association, the Southern California section of the American Chemical Society, growth of the oil industry of California, mining industry in relation to state accident insurance, oil engines operating on the Deisel principle, and silt problem of the Colorado river. There is also a map of the southwest included.

Nevada County

Gold-bearing quartz has been cut at 300 and 710 ft. in the Union Hill mine, and is an important development. A. D. Cox is in charge of the property, which is fully equipped with a 20-stamp mill. It is owned by San Francisco and Los Angeles people.

Shasta County

San Francisco people are thoroughly reopening the old Niagara mine.——A diamond drill is exploring the Franklin claim of the Milkmaid Mining Co. The shaft is to be sunk deeper. H. F. Musser is manager.——Work will probably be resumed at the Afterthought copper mine near Ingot.——The Mammoth company's smelter produced 1,100,000 lb. of copper in November.

On Wednesday last, December 2, Judge W. C. Van Fleet, accompanied by his staff, officials of the farmers' association, Mammoth Copper Co., and others interested, inspected the smelter and bag-house of the Company at Kennett. Demonstrations on a working scale were given, showing the effect of the bag-house on fume from the furnaces.

Solano County

In the suit of residents of Benicia and adjacent agricultural land *v.* the Selby Lead & Smelting Co., regarding alleged damage done by fume from the latter's smelter on San Francisco bay, the commission of investigation, consisting of J. A. Holmes, Edward C. Franklin, and Ralph R. Gould, reports that the Company has changed its mode of operation since the suit started in 1905, and can operate within the terms of the 1906 injunction. By installing the Cottrell process, a bag-house, new roasting system, and sending certain ores to other smelters, the difficulties have been met.

Tuolumne County

(Special Correspondence.)—It is reported that a rich discovery has been made in the Mohican mine, situated a few miles southeast of Tuolumne. During recent years work has been conducted on a small scale under the direction of R. E. McHale, superintendent.——The Tuolumne Deep Channel Mining Co. has suspended operations at its property near Confidence until next spring. Prospecting has been done with a Keystone drill, and it is said results so far have been most encouraging.——The Peoria Flat gravel mine, recently bonded by William Pereira to R. A. Lewis and others, is to be the scene of extensive mining operations. A number of buildings have been erected for the accommodation of the men employed and for other purposes, and a traction steam-shovel of great capacity, a Quenner gravel mill, and other machinery have been taken to the property. The gravel deposits are large, and good prospects have been obtained in the tests made.

Sonora, November 28.

Active work is under way at the Republican property of five claims. Over 4500 ft. of development has been done to 700 ft. depth, and the gold output is over $300,000. The Mammoth claim is sending good ore to the mill.

The injunction suit against the Mammoth company was

resumed at San Francisco on December 8. A large number of farmers, fruit growers, and stockmen from the county are present at the hearing.

COLORADO

Fremont County

After 17 days of examination, during which time 440 veniremen were questioned, a jury was secured at Canon City on December 4 for the trial of the seven members of the United Mine Workers of America who are charged with the killing of William King, a non-union miner, in connection with the attack on the Chandler mine last April. The taking of testimony began on December 7.

Ouray County

It is estimated that this county will produce a total of $1,980,000 from its gold, silver, lead, copper, and spelter this year, an increase of about $510,000 over that of 1913. The tonnage was 97,336 in 1913, and estimated at 135,000 in 1914.

The Camp Bird company reports as follows for the third quarter of 1914: Development totaled 795 ft. Work on the hanging-wall orebody shows an average length of 130 ft. On No. 6 level east No. 2 the shoot is 165 ft. long, 3 ft. wide, assaying $30 per ton. On No. 8 level, the east heading was advanced 194 ft. in vein formation, of which 150 ft., as shown by cross-cuts, is from 20 to 30 ft. wide. In the last 44 ft. it has narrowed considerably. The formation is quartz, worth nothing except where associated with hematite, which assays from $20 to $100 gold per ton. This mineral occurs in wavy streaks of great irregularity, and in bunches 10 to 30 in. wide, it being better on the floor of the level. The ore is very hard, and that mined varies from the sample plan. The stamp-mill crushed 7843 tons of ore, yielding $235,023 from bullion and sale of concentrate. The net profit was $125,000, and $72,000 from the Santa Gertrudis company of Mexico.

Shipments from Ouray during November were as follows: crude ore, Wedge, 195; Wewissa, 10; and Bachelor-Khedive lease, 27 tons; concentrate, Camp Bird, 495; Wanakah, 328; Atlas, 214; and Cumberland, 33 tons; and matte, Wanakah, 196 tons.

Fire at the Revenue mine destroyed buildings and stores worth $5000 last week.

Teller County (Cripple Creek)

The gold output of the district in November is estimated as follows:

Plant.	Tonnage.	Av. val.	Gross val.
Golden Cycle	29,000	$20.00	$ 580,000
Portland (Colorado City)	9,820	20.00	196,400
Portland (Cripple Creek)	16,550	2.85	47,167
Smelters	4,300	55.00	236,500
Colburn-Ajax	4,900	7.50	36,750
Stratton's Independence	9,142	2.16	17,587
Neville-Free Coinage	800	5.00	4,000
Gaylord-Dante	1,500	2.50	3,750
Wild Horse	1,000	3.00	3,000
Kavanaugh-Jo Dandy	1,400	2.00	2,800
Isabella	950	2.00	1,900
Total	79,362		$1,129,854

This yield was about $20,000 above that of October, in spite of a shorter month and one holiday, also the El Paso fire.——Dividends were as follows: Golden Cycle, $300,000; Elkton Consolidated, $50,000; and Gold King, $10,000. On December 19 the Vindicator mill distributed $90,000, this being an 'extra' of 6c. per share. The Golden Cycle company's distribution this year totals $1,005,000.

A 100-ton mill and cyanide plant is to be built by the Gold Bond Leasing & Development Co. on Gold hill. The plant will cost about $60,000. S. L. Herber is superintendent. Besides a large tonnage of $4.50 to $6.40 ore in the mine, dumps contain about 75,000 tons averaging $3 to $5 per ton.

IDAHO

Shoshone County (Coeur d'Alene)

Dividend No. 207, equal to $81,750, was paid by the Bunker Hill & Sullivan company on December 4. The total to date is $15,710,250.——A rise from No. 4 adit of the Tuscumbia mine, in Sunset peak near Wallace, has opened a large orebody.

The Morning mine of the Federal Mining Co. has been closed, putting 125 men out of work. This is due to low-grade ore and the low price of lead. This mine and its mill were a great support to the town of Mullan.——After being closed for six months, the Federal company's Frisco mine, at Frisco, was reopened last week. The mill has been altered to suit the refractory ore, including a process of drying and slightly roasting, with magnetic separators.——Three feet of high-grade mill ore has been cut in the Nabob on Pine creek.——Net profit of the Stewart, near Kellogg, is said to have been $100,000 in November.

MISSOURI

Jasper County

The Southwest Missouri Mine Safety and Sanitary Association has been formed at Joplin. Thirty operators attended the organization meeting on November 28; also Edward Higgins of the U. S. Bureau of Mines, and A. J. Lanza of the U. S. Department of Public Health. Fourteen important mining companies have become members of the society. H. I. Young, of Webb City, is president; W. A. Rhea, of Carthage, secretary; and T. J. Munson, of Webb City, treasurer. The object of the Association is to lessen the tuberculosis among miners of the zinc-lead mines. Mr. Higgins said that four important things should be investigated: a water supply for every working face in the mines, no squibbing or boulder blasting while the men are underground, a thorough wetting of the faces every morning, and the improving of ventilation.

The McDonald Mining Co., operating a lease of the Connor land, has bought the Portland 300-ton mill, northeast of Carterville, from the Landreth Machinery Co. It will be reconstructed in about two months. Sheet-ore formation in the area worked by the McDonald company occurs at 195 to 208 ft. depth, and the weekly output is 60 tons blende and 20 tons of lead.

MONTANA

A new map of this state, in two sheets, each 40 by 46 in., has been issued by the U. S. Geological Survey, price 45 cents. It contains the latest information connected with mining, railways, rivers, etc.

The Anaconda Copper Mining Co., on November 30, paid taxes amounting to $675,739 in 18 counties of the state, of which nearly half was in Silverbow county. This was $76,794 less than in the previous year.

Silverbow County

Taxes paid by the Butte & Superior Copper Co. on November 30 totaled $28,300; and the North Butte Mining Co. about $11,000.——The estate of F. August Heinze is indebted to the defunct State Savings Bank at Butte for $221,292, according to the first report of the receiver, F. D. Williams.

The suit of the Clark-Montana Realty and Elm Orlu Mining companies against the Butte & Superior Copper Co., involving apex rights to the Rainbow vein of the Black Rock claim, has been set for hearing June 15, 1915, by federal Judge George M. Borquin.

NEVADA

Esmeralda County

The estimated output of the Goldfield Consolidated in November is $327,000 from 28,390 tons of ore, yielding a profit of $143,000.——The net realization from the Jumbo Extension last month was about $100,000, $24,000 over that of October.

Five to six feet of $158 to $183 ore is being broken from drifts off the vertical rise. These developments in the Velvet claim of the Company are attracting considerable attention.——Six feet of $12.20 ore has been cut at 590 ft. in the Booth mine. ——At 250 ft. in the Florence, 15 ft. of quartz has been opened worth $4 to $25 per ton.——The new shoot at 500 ft. in the Silver Pick is improving.

HUMBOLDT COUNTY

The ore-shoot in adit C of the Nevada-Packard lease is a remarkable one. Ore worth $34,549 has been extracted during the past two months.

LINCOLN COUNTY

The country near the Black Ledge winze has been drained to the level of No. 1 shaft of the Amalgamated Pioche, about 1425 ft. deep. No. 14 level was connected with the winze, and good ventilation resulted. Mining can now be done economically below 1200 ft. Rise No. 5 from this level is in good zinc ore.

NYE COUNTY

Three mills at Manhattan have produced $167,436 from 45,429 tons of ore during 11 months of the current year. About 15,000 cu. yd. of gravel was sluiced at the placers, yielding $45,000. Most of the deep gravel properties in the main gulch have been worked out under the present method of operation.——The White Caps mine is estimated to contain $300,000 of ore, averaging $17 per ton, to the 200-ft. level. This ore is refractory.

Six Tonopah mines yielded 9448 tons of ore, worth $186,024, last week.——Forty stamps and four tube-mills are now working at the Extension mine, crushing 235 tons per day. Eight concentrating tables, a Dorr thickener, and six zinc boxes were added to the old plant, with the 10 stamps and a tube-mill.—— The Jim Butler *v.* West End suit started on December 7. A new head-frame is being erected at the Jim Butler by Campbell & Kelly.——Six feet of good ore has been cut by rise 579 in the West End.——The Montana has made a shipment of 31 bars of bullion worth $23,000.

Interesting prospecting continues at Tonogold.——The

TONOGOLD, NEAR TONOPAH. HEAD-FRAME IS ON THE CAMPBELL & KELLY LEASE.

Campbell & Kelly lease is down 82 ft. in good looking quartz. This claim is equipped with a hoist.——Cross-cutting is under way at 55 ft. in the Miner.——A whim is to be erected at the Last Chance, which is down 45 ft.——Mineralized formation, similar to andesite in the Midway at Tonopah, is being driven on in the Rabbit Foot.

WHITE PINE COUNTY

(Special Correspondence.)—After considerable discussion, the State Tax Commission has reduced, after raising it to $1,500,000, the Nevada Consolidated assessment to $1,000,000. The county commissioners agreed to cut their 1915 budget $20,000. This action, it is thought will allow the Company to continue work; otherwise there was a disposition to shut down and contest the increased tax, which is unjust. The Company would prefer to produce copper here rather than in Utah plants. All married men are working nearly full time. The Company is installing oil flotation machines in No. 2 unit of the mill.

The driller of the county well for artesian water lost the hole and casing at 703 ft.——On the Jennie A. mine at Hamilton, mining is stopped and the owners are jigging the dump. ——The U. S. government well, on Black Rock desert, was put down to 1500 ft. The casing has been left in the well, so as to go deeper if desired.

Ely, November 27.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—Heavy shipments of silver-gold bullion and concentrate have been made from Mogollon of late, the Ernestine sending 16 bars on November 19, and the Socorro 12 bars and 5 tons of concentrate on the same date. The

SHIPMENT OF SILVER-GOLD BULLION FROM THE MOGOLLON DISTRICT, SOCORRO COUNTY, NEW MEXICO, THROUGH SILVER CITY. WEIGHT, 3159 LB., OR 45,800 OZ., WORTH $42,485.

cyanide situation is somewhat acute there.——The Mogollon mail contract has been let by the government to C. A. Bennett of Silver City at $10,000 per year, until June 1918. After January 1, 1915, there will also be a telephone exchange at Mogollon.

Mogollon, November 24.

OREGON

BAKER COUNTY

There are several promising mining claims on the side of a mountain in the Greenhorns, west of Sumpter, known as Olive Butte, especially the Big Elk mine.——The Greenhorn district seems to be more prosperous than usual. The new 10-stamp mill of the Golden Gate is about finished.——The Powder River Gold Dredging Co. has been granted permission to allow its boat to cut through a county road near Sumpter. The road must be remade and $50 paid for the privilege.

SOUTH DAKOTA

LAWRENCE COUNTY

The Homestake Mining Co. has published the following notice: "Additional wages, amounting to 7% of the total wages paid for the year 1914, will be paid to all employees whose names are on the December 1914 payroll. Checks for the amount payable will be delivered on the regular pay-days in January 1915." This is a regular distribution now.

UTAH

Juab County

Following a visit of George Dern, Theodore P. Holt, and James Dick to the Tintic district, is a rumor that a mill similar to that erected at Park City by these mining men may be constructed at Tintic. A good deal of experimental work is being done in the district generally.——Sulphide ore has been opened at 1900 ft. in the Iron Blossom. The annual meeting of the Iron Blossom Consolidated Mining Co. was held at Provo on December 5. Dividends paid during the year amounted to $400,000, and on December 1 there was $340,000 cash on hand.

Millard County

The Westwood Oil Co., owning land north of Fillmore, is to resume drilling. Three rigs will be working in a week or two. One well is down 1120 ft., and shows oil from 600 ft. G. W. Westphal is in charge.

Salt Lake County

The Utah-Apex Mining Co. made a net profit of $49,651 during the third quarter of 1914. Development during the year ended August 31 cost $48,850. A good tonnage of ore has been opened. Generally the year was a profitable one.——In enlarging the mill it was necessary to suspend treatment for two months, while the search for a bandit also resulted in a complete shut-down of the mine and mill. The revenue from 121,675 tons of ore and royalty was $916,907. The gross profit was $167,467. Owing to the low price of lead the earnings were considerably lower than usual.——Ohio Copper shares are only worth 15c. each, compared with $8 before reorganization, making the entire property valued at $187,500, about 10% of what the equipment cost.——Ore worth $40 per ton has been opened for some distance by T. W. Blake, a lessee in the Wasatch Mines Co.'s property, in the Alta district.

Summit County

At the Daly West, the new hoist and compressor are ready for work. Second-class ore is being sent to the new mill.

CANADA

British Columbia

Ore shipments from Rossland mines are increasing, and during November the Consolidated smelter at Trail received 24,485 tons, 4775 tons more than in October. Contributors were as follows: Centre Star, 13,150; Le Roi, 10,100; Josie, 1235; and United Copper at Chewelah, Washington, 701 tons.

The annual report of the West Kootenay Power & Light Co. shows that the revenue-producing load was 8029 hp. Gross revenue from all the subsidiaries was $175,788, and expenditure $119,718. The sum of $248,474 was brought forward from the previous year, and the total on hand was $302,061. The preferred stock 7% dividend amounted to $34,600, and common stock 5%, $100,000. Assets are $4,436,179. A third unit, of 8000 hp., was installed during the year.

Ontario

Bullion shipments from Cobalt last week totaled 83,234 oz. ——No. 4 shaft of the Conlagas mine is down 225 ft., equal to the fourth level of the main mine.—Seven inches of 3000 to 4000-oz. ore is being opened at 460 ft. in the Beaver. This shoot was opened at 530 ft. some time ago.—The most important work in the Temiskaming is at 750 ft. Drills are working at 350, 575, and 650 ft. Twenty stamps are crushing ore.

During the four weeks ended November 4 the Hollinger mine produced $162,885 from 18,645 tons. Operating costs totaled $4.48 per ton. The surplus is $1,173,640.

Yukon

The Yukon river closed in front of Dawson at 10:26 a.m. on November 15, the latest recorded by three days. No damage was done by ice jams.

PERSONAL

J. H. Mackenzie is in New York.

B. B. Thayer has gone to Montana.

C. W. Merrill has gone to New York.

H. K. Rogers was in New York last week.

A. B. Wolvin has been in New York on business.

Kuno B. Heberlein was in New York and has gone to Mexico City.

H. F. Grondys, manager for Cia. Minera de Oruro, is visiting mines through the West.

James C. Ray has just returned from professional work in the northern part of California.

Information is wanted of the present whereabouts of J. S. Neall, last heard from at Goldfield, Nevada.

John M. Callow, president of the General Engineering Co. of Salt Lake City, left recently for New York.

William Wallace Campbell will lecture before the National Academy of Sciences on 'Stellar Evolution and the Formation of the Earth.'

J. H. Riddle, general manager for the Nevada Cinnabar company, is at the plant near Ione, Nevada, where he expects to be for a month.

George Gless was in New York, on December 2, to attend the meeting of the New York section of the American Institute of Mining Engineers.

S. H. Brockunier, of Nevada City, California, is at Cave Creek, Arizona, making an examination of the property of the Pittsburgh Tungsten Mines Company.

J. Kojima, metallurgist for the Furukawa Mining Co., having completed his tour of mining districts in this country, sailed from San Francisco for Japan on November 28.

Owen Letcher, of the editorial staff of *The South African Mining Journal*, and contributor to the *Press*, has joined the South African forces fighting in German Southwest Africa.

Among Utah men to attend the meeting of the American Mining Congress at Phoenix were George H. Dern, R. J. Evans, Arthur Thomas, W. H. King, Ernest Gayford, Ernest L. Gobbe, H. S. Joseph, J. T. Hodson, Charles Moore, Jesse Knight, W. Lester Mangum, and L. A. Friedman.

Obituary

John Denton Feidt, who died at Bellevue Hospital, November 23, was one of the pioneer miners and contractors of the West. After experience in convoy of wagon-trains and other characteristic work of pioneer days, he went to Montana in 1864. He was one of the discoverers of the Big Bowl Basin mines at the head of the Missouri river and later of the Big Bear Gulch mines. In 1869 he went to New York, by way of San Francisco and Panama, with $40,000 in gold dust as a result of his work, but the lure of the West drew him back, and from 1870 to 1882 he carried on contracting work at various points in the Western States and territories. In 1882 he was locating claims at Leadville, and in 1888 building water works at Chicago. Later he studied the zinc deposits of Arkansas and grew oranges in Florida. His last years were passed at Clearspring, Maryland, surrounded by friends, busy and happy. He was an early convert to Mr. Carnegie's philosophy that one should give while still living, and he accordingly divested himself of almost all of his large fortune, retaining merely sufficient to meet his needs. He was born in 1837, and his long busy life covered the period of maximum expansion of pioneer work in which he and men of his type found a fitting field for their restless energy.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, December 10.

Antimony	15 —15¾
Electrolytic copper	13¼—13½
Pig lead	4.05— 5.00
Quicksilver (flask)	$52.50
Spelter	6½— 6¾
Tin	34½—36
Zinc dust, 100-kg. zinc-lined cases	10

EASTERN METAL MARKET.

(By wire from New York.)

NEW YORK, December 10.—Copper is quiet but firm, lead is also quiet, while spelter is strong. Calumet & Hecla company has passed its dividend, the second time this year.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending

The New York letter of this issue discusses several points regarding this metal. The Anaconda output in November was 12,700,000 lb., compared with 11,800,000 lb. in October, and 25,250,000 in November of 1913: The market was firm last week, advancing continuously until the end of the week. The Italian steamship lines have agreed to accept shipments of copper, but insurance is hard to get. The visible supply in England, France, and afloat thereto is given as 30,626 tons on December 1, a decrease of 216 tons during the two weeks preceding, but above the average for thia year.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slighly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb, are given below:

Week ending

As discussed in the New York letter of this issue, the exports to Europe are making a strong market. The total for the past three months is more than that for seven years. Blende has been selling for $43 to $46.50 per ton, basis of 60% metal, at Joplin. This week last year the price was $37 to $39.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.

Tin is quiet at 32 to 33c. per pound, and £146 per ton for spot metal in London.

SPECIE MOVEMENTS

Exports of gold from New York for the week ended December 5 were $100,000 to Vera Cruz; of silver, $619,671, mostly to London. Since January 1 the total is $128,324,883 gold and $40,238,062 silver, against $69,211,146 and $45,936,874, respectively, for the same period of 1913. Imports of gold at New York last week were $197,180, and silver, $483,270. Since January 1 the total is $9,188,997 gold and $9,917,981 silver, against $24,659,661 and $10,375,604 in that period of last year.

OIL STATISTICS

The following data covering the year 1913, is from the U. S. Geological Survey:

Final figures of the production of petroleum of the United States and the world are now at hand in the 356-page bulletin by David T. Day. This publication covers everything connected with the oil industry.

A study of the domestic production shows a story of progressive maxima for the past seven years, until in 1913 the product reached 248,446,230 bbl., or 33,126,164 metric tons, while in 1912 it was 222,935,044 bbl., or 29,724,673 tons. In the previous year the value was $164,213,247, or 73.7c. per bbl., against $237,121,388, or 95.4c. per barrel in 1913.

As to the production of individual fields, there was no variation in their relative importance. It is noteworthy that the normal decline in the oilfields of New York and Pennsylvania was changed into a slight increase under the spur of greatly increased prices. West Virginia and Ohio declined, but only slightly. Even in Indiana the decrease was subnormal, because of new developments on the western border of the state. The decline in Illinois was decided, nevertheless 'wild catting' is still active in many widely separated regions of the state. The great gains in production came from the Mid-Continent fields and from California. A large flow was struck in a well on the edge of the Cushing region, which started a general policy of drilling to the thick and prolific Bartlesville sand, and oil came with a rush. Stocks were accumulating heavily at the end of the year. At the close of 1912, consumption in California had so nearly balanced production as to encourage the producers, and to defeat concerted effort toward the restriction of drilling. Many of the wells in 1913 were gushers of the phenomenal type, and aided greatly in increasing the supply. As to Texas and Louisiana, the Electra and Burkburnett fields in the former state progressed satisfactorily, and a new area was developed at Moran.

Stocks in the United States at the end of 1912 and 1913 amounted to 122,869,702 and 122,934,188 bbl., respectively, which is considered extraordinary, taking into account the large production. These stocks are equal to about six months' supply, which California oil men think is necessary to be on the safe side. The value of raw material in such stocks is about $125,000,000, a hazardous investment of money which has not proved tempting in any country except the United States. Of the stocks held at the close of last year, 48,302,392 bbl. was held in California (now about 57,000,000 bbl.), 53,749,257 bbl. in Kansas and Oklahoma, and 8,243,421 bbl. in Illinois.

Production by states in the past two years was as follows:

	1912		1913	
State.	Quantity.	Av. price per bbl.	Quantity.	Av. price per bbl.
Alaska	(a)	.....	(b)	.....
California	(c)87,272,593	$0.454	97,788,525	$0.467
Colorado	206,052	0.973	188,799	0.926
Illinois	28,601,308	0.851	23,893,899	1.296
Indiana	970,009	0.913	956,095	1.337
Kansas	1,592,796	0.688	2,375,029	0.947
Kentucky	484,368	0.877	524,568	1.288
Louisiana	9,263,439	0.758	12,498,828	0.981
Michigan	(d)	.....	(b)	.....
Missouri	.....	.....	(b)	.....
New Mexico	.....	.....	(b)	.....
New York	874,128	1.604	902,211	2.404
Ohio	(e)8,969,007	1.347	8,781,468	1.997
Oklahoma	51,427,071	0.674	63,579,384	0.937
Pennsylvania	7,837,948	1.644	7,963,282	2.487
Texas	11,735,057	0.754	15,009,478	0.978
West Virginia	12,128,962	1.643	11,567,299	2.492
Wyoming	1,572,306	0.507	2,406,522	0.493
Other states	.....	.....	(f)10,843	1.777
Total	222,935,044	$0.737	248,446,230	$0.954

(a) Included in California. (b) Included in other states. (c) Includes Alaska. (d) Included in Ohio. (e) Includes Michigan. (f) Includes Alaska, Michigan, Missouri, and New Mexico.

The well record for the past two years was as follows:

Year.	Oil.	Gas.	Dry.	Total.
1912	12,514	1,811	2,855	17,180
1913	19,101	2,207	4,282	25,590

A review of foreign oilfields includes the following notes. In Canada, exploration for oil and gas was done in Manitoba and Alberta, with excellent results. Work in Mexico was active in spite of unsettled conditions. Trinidad's output increased. Central America attracted attention. The industry in Peru is making rapid progress, especially the Lobitos field. The older districts of Russia continued to decline, but prospecting in the Ural-Caspian region gave encouraging results. The Baku field yielded 48,563,985 bbl. Galicia, in Austria-Hungary has been declining continuously since 1909 at the rate of about 2,000,000 bbl. per year, but last year it was less than 1,000,000 bbl. In spite of the Balkan war, Rumania increased its production. Burma also had an increase and the Dutch East Indies. Exploration has been done in many other countries with fairly satisfactory returns.

The world's production of crude petroleum in 1913 and in 1857-1913, by countries, in barrels and metric tons, is as follows:

	Production, 1913			Total production, 1857-1913		
Country.	Barrels.	Metric tons.	Percentage of total.	Barrels.	Metric tons.	Percentage of total.
United States	248,446,230	33,126,164	65.12	3,069,694,605	409,292,614	59.16
Russia	60,935,482	8,124,731	15.97	1,553,314,449	207,108,593	29.93
Mexico	25,696,291	3,426,172	6.74	68,965,294	9,195,373	1.33

BOOK REVIEWS

PETROLEUM YEAR BOOK, 1914. Compiled by Sydney H. North. P. 104. Index. Wilkinson Bros., Ltd., London, 1914. For sale by the *Mining and Scientific Press*. Price $2.

This is a decidedly useful little book on an important product, the world's output of which in 1913 was 382,961,526 bbl., or 51,704,951 tons. Briefly, the work contains the following information in concise form: Statistics relating to the yield of each oil-producing country, with prices; asphalt and shale mined; imports of petroleum products; geology of the oilfields of the world; chemistry of various oils; use of oil fuel and types of burners; oil-engines; and miscellaneous data.

ELECTRICITY IN COAL MINING. By David R. Shearer. P. 84. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by the *Mining and Scientific Press*. Price $1.50.

While the use of electric power in coal mines is not without a certain amount of danger, yet its use is making headway and the power finds an increased demand. This is so in Pennsylvania especially, and notes on this subject have appeared in recent issues of the *Press*. About coal mines electricity is used for hoisting, pumping, ventilating fans, signaling, coal-cutting machinery, in locomotives instead of mules for haulage, and many other purposes. Types of generating plant suitable, motors and haulage equipment, operation of coal-cutters, and other information are given in a practical manner.

ASSAYING IN THEORY AND PRACTICE. By E. A. Wraight. P. 323. Ill., index. Longmans, Green & Co., New York, and Edward Arnold, London, 1914. For sale by the *Mining and Scientific Press*. Price, $3.

This is an addition to the already large number of books on this subject. It covers both dry and wet methods, more especially those needed by laymen and the mine assayer. These methods are those taught by the author at the Royal School of Mines during the past 12 years, and with which he has had actual practical experience. The arrangement of the book is somewhat new. It opens with tables of the elements, weights and measures, logarithms, list of apparatus and chemicals necessary, and minerals and their characteristics, which are generally found at the end of most books. In the former position they attract the immediate attention of the student. Chapter II gives some hints for prospectors, and the next chapter is on the important subject of sampling. Then follow the dry assays of lead, tin, gold, silver bullion, mercury, and the examination of solid fuels and refractory materials. Part III deals with the analysis of iron, copper, zinc, and aluminum, lead and bismuth, tin, arsenic and antimony, manganese, chromium, sulphur in ores, vanadium, uranium, and molybdenum, and cobalt and nickel. The concluding chapters describe mill and cyanide testing by the newest methods. The index is very complete, and the book of practical value.

GREAT COLLIERY EXPLOSIONS, AND THEIR MEANS OF PREVENTION. By W. Galloway. P. 130. Ill., plans.. The Colliery Guardian Co., Ltd., London, E. C.

Unfortunately, explosions occur far too frequently in coal mines, usually with a great loss of life. No particular field in the world is free from them, hence their causes, and steps taken to minimize further occurrences have been the subject of considerable investigation. The author has had a long experience with collieries, and has been insistent on the elimination of dust from the main drifts of these mines. This book is partly made up of papers prepared for the Royal Society, and Royal Meteorological Society. Fire-damp was generally supposed to be the principal agent in all great colliery explosions, although they took place in well ventilated workings. In 1875 the author was convinced that coal-dust was the main source of trouble, and fire-damp a secondary one. The papers discuss the connection between explosions in collieries and weather, experiments with safety lamps, the influence of coal-dust in colliery explosions, and notes on commissions. The explosions described are accompanied by plans. An interesting book for coal operators and others.

U. S. Geological Survey publication, Washington, D. C., 1914: PRODUCTION OF PETROLEUM IN 1913. By David T. Day. P. 356. Charts and table. Each year this bulletin grows in size, and is a most valuable publication. An extensive extract from this book appears on the page ahead.

MINING DECISIONS

MINING CLAIM—AMENDED LOCATION

Where, between the dates of the original location of a mining claim and an amended location thereof, the claim was included within an area withdrawn by competent authority from appropriation under the mining laws, no rights attach by virtue of the amended location to such portions of the vein or lode claimed thereunder as were not included in the original location, so long as the withdrawal stands; and as no lawful purpose would therefore be subserved by a survey of the amended location, the Land Department will not direct such survey to be made.

United States Phosphate Co. (Land Department), 43 Land Decisions, 232. April 27, 1914.

MILLSITE IN NATIONAL FOREST

A decision by the Department of the Interior canceling a millsite entry, without passing upon the validity of the millsite claim or location, or the claimant's possessory rights or ownership in the premises, in no wise affects the legal rights, if any, the claimant may have in the millsite claim; and where the land is included within the limits of a national forest, but excepted from the operation of the proclamation creating the same, by reason of the millsite location, the subsequent cancelation of the millsite entry does not have the effect to make the land a part of the national forest, or deprive the Secretary of the Interior of jurisdiction to reinstate the canceled entry with a view to the issuance of patent thereon.

Alaska Copper Co. *et al.* (Land Department), 43 Land Decisions, 257. May 28, 1914.

PLACERS IN STREAM BEDS

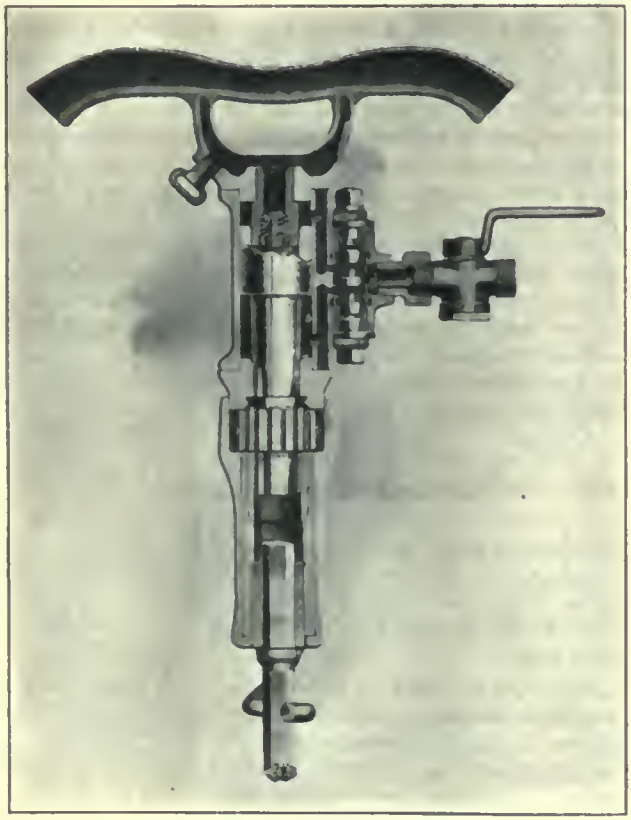
The banks and beds of non-navigable, unmeandered streams, on lands belonging to the United States, containing valuable mineral deposits, may be included in locations and entries under the mining laws. The general mining laws are operative with respect to deposits of gold within the limits of national forests or power-site withdrawals the same as with respect to like deposits elsewhere on the public domain. Such lands when containing mineral of such quantity and value as to warrant a prudent man in the expenditure of his time and money, with a reasonable expectation of developing a profitable mine, are disposable only under the mining laws, notwithstanding they may possess a possible or probable value for power-site purposes; but by the Act of August 24, 1912, lands withdrawn under the act of June 25, 1910, are open to location and acquisition under the mining laws, so far as the same apply to metalliferous minerals.

Cataract Gold Mining Co. *et al.* (Land Department), 43 Land Decisions, 248. May 26, 1914.

New Machines and Devices

Sullivan 'DP-33' Rotator

Among new drills recently put on the market is a Sullivan rotating hand hammer drill having several new features. This drill is constructed of steel throughout, with all parts, excepting the handle, hardened and ground on all bearing or wearing surfaces to accurate size. The standard chuck bushing with which the machine is equipped, accommodates both solid and hollow drill steel with a ⅞-in. hexagon shank 3¼ in. long, measured from the striking end to the collar. The drill uses the same steel as the Ingersoll 'Jack-



CROSS-SECTION OF 'DP-33' DRILL.

hamer' steel. The collar below the shank is 1⅝ in. diameter and ½ in. long, with square shoulders filleted into the steel body. The machine may be operated with either steam or air, but when a steam drill is required, it must be specified, as the auxiliary exhaust ports in the cylinder adapted for use with steam are not drilled on air machines.

The following table covers general specifications:

Cylinder diameter, 2¼ inches.

Length of working stroke, 2⅜ inches.

Total length of stroke, 2⅝ inches.

Weight of machine with throttle valve and steel retainer, 38 pounds.

Size of air hose required, ¾ inch.

Standard size of drill shanks, ⅞ in. hexagon by 3¼ in. long.

Air consumption in cubic feet free air per minute at 85 lb. pressure, 70 feet.

Boiler horse-power, 5.

Depth to which machine will drill easily, 8 ft. and up, depending on nature of ground.

The following is a list of the characteristic features of the drill: Automatic rotation of drill steel; drill steel retainer; Sullivan differential valve motion; removable valve bushings; valve chest integral with cylinder; automatic lubrication; removable chuck bushing; Sullivan roller ratchet; positive rotation; absence of separate riffle bar; use of exhaust air for cleaning drill hole; minimum vibration; low power consumption; minimum number of parts; and maximum durability.

WITH WATER ATTACHMENT DRILLING HOLES TO A DEPTH OF 30 FEET.

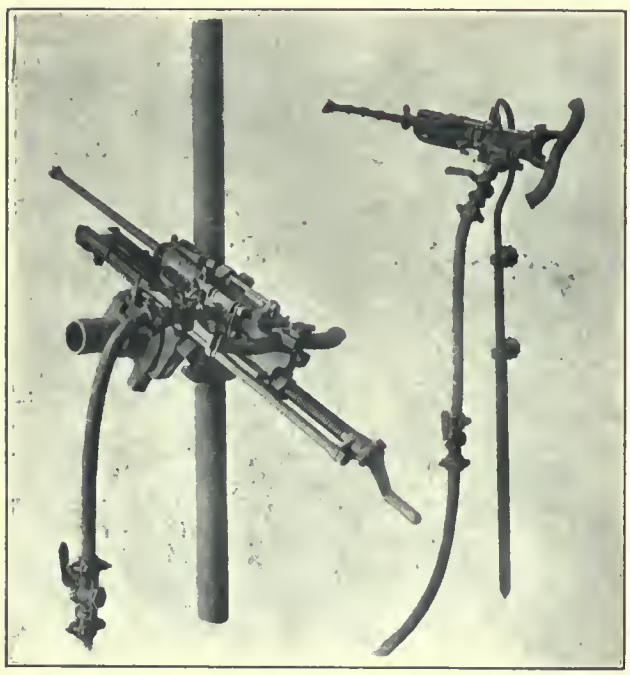
The rotation of the drill steel is accomplished by the use of spiral and straight flukes or grooves milled on the contracted or striking end of the piston. The straight grooves fit correspondingly shaped projections in the opening of the retaining bushing, which is secured in the chuck of the machine, and the spiral grooves fit correspondingly shaped projections in the opening of the oscillating ratchet which is between the chuck and the front end of the cylinder. As the piston reciprocates, a step-by-step rotary movement is transmitted to the piston and chuck of the machine, which in turn receive the drill steel. This principle of rotation dispenses with the separate fluted bar and confines the rotating parts to the front of the machine so that the work of turning the drill steel is accomplished in the most direct manner when the piston moves rearward in the cylinder. The standard

Sullivan solid ring ratchet is employed, having flat springs and roller pawls similar in all respects to the rotating device employed on the reciprocating type rock drill, except that a positive means is provided to prevent the ratchet ring from slipping, instead of depending upon friction.

The drill-steel retainer consists of a U-shaped yoke, adapted, when in the normal position, to engage the drill steel directly below the collar. This U-shaped yoke is suspended by arms from trunnions mounted in suitable sockets upon the side rod springs, in such a manner that the normal compression of the springs acts to keep the yoke of the retainer constantly engaged with the drill steel; but it may readily be disengaged by hand and the drill steel removed when necessary.

The standard Sullivan differential valve motion is employed. The valve chest, however, is forged integrally with the cylinder, and the valve is housed in removable hardened steel bushings by buffer plugs held in position by yoke springs and side rods. The air inlet connection is bushed with a hardened steel inlet nipple, which preserves the threads of the valve chest.

The Sullivan standard automatic lubricator is contained in



TWO METHODS OF MOUNTING.

the base of the handle, differential pressure being employed to cause minute particles of oil to be fed, at every stroke of the piston, into the cylinder, where it commingles with the inlet air and is distributed in the form of a spray over all working parts, thus insuring positive and adequate lubrication when the machine is in operation, and then only. A removable chuck bushing provides a means for keeping the drill shank in alignment with the piston, and by an ingenious arrangement the chuck is housed in such a way as to prevent any possibility of rock cuttings or foreign material finding their way into the bearing of the chuck in its housing.

In common with all types of Sullivan hand-operated hammer drills, exhaust air only is used in connection with hollow drill steel for the purpose of ejecting the rock cuttings from the drill-hole, and the volume of air used for this purpose may be regulated at will by placing a hand over the exhaust opening in the valve chest. When steam is used for operating, it is desirable to keep the drill-hole flooded with water, and on horizontal or up-hole work spiral drill steel is recommended.

Plain pneumatic hose, $\frac{3}{4}$ in. and 3 ply, is used for supplying air to the machine, and $\frac{3}{4}$-in., 7-ply cotton-woven jacketed hose is supplied when steam is used, in 25 or 50 ft. lengths as desired. Four types of drill steel are used with this machine, namely: $\frac{7}{8}$-in. hexagon hollow drill steel, sharpened with a six cutting-edge rose bit; $1\frac{3}{16}$-in. solid spiral drill steel sharpened with 'Z' bit; $1\frac{3}{16}$-in. hollow spiral drill steel sharpened with 'Z' bit; and $1\frac{1}{4}$-in. solid twisted spiral sharpened with fishtail bit.

For the purpose of supporting the machine when holes directed at or above the horizontal are to be drilled, or when the machine is to be operated under conditions which make it impractical for the operator to hold it by hand, the 'telescopic support' and the 'cradle mounting' may be used to advantage. The telescopic support, as the term implies, is a light, portable, telescopic column with the piston ending in a hook. The drill is suspended from the hooked end by a clamp connection engaging the side rod of the machine. In the lower part or cylinder of the support is a spring of sufficient strength to support the weight of the machine. The operator adjusts the support to the required height and collars the drill-hole, after which the hand screw is released and the drill is thus supported upon the spring. Proper alignment of the drill-hole is maintained by pressing the machine down slightly against the spring support. This type of support is recommended for use where the ground is reasonably soft and the time required to drill a hole to the required depth prohibits the use of a more substantial form of support or mounting.

For drilling under the foregoing conditions in hard ground where a rigid form of support is desirable, the cradle mounting is recommended, which consists of a light rock-drill shell with the ordinary feed screw and crank handle, supporting a cradle upon which the drill is secured by bolt and strap connection. For ordinary down-hole work, the machine is guided by hand, the operator merely exerting a slight downward pressure against the drill.

The description of the drill together with the illustrations are published through the courtesy of the Sullivan Machinery Co. of Chicago.

Commercial Paragraphs

The WEBSTER MANUFACTURING CO., Tiffin, Ohio, in the November number of the *Webster Method*, publishes an illustrated article on 'Sand and Gravel Washing in Cleveland.' Conveyor systems are also discussed in two articles on the handling of clay and coal.

STANDARD OIL COMPANY OF CALIFORNIA, in its monthly bulletin, publishes among other articles an interesting discussion on a new method for extinguishing oil fires. Statistics on the world's production of crude petroleum from the year 1857 through 1913 are also presented in detail.

Announcement is made that the partnership formerly known as Hegeler Brothers, which has operated a zinc smelter at Danville, Illinois, for a number of years, has been reorganized into a new corporation called THE HEGELER ZINC CO. This business will be continued under the same management and with the same policies as the old firm. Julius W. Hegeler is president of the new corporation.

The WESTERN ELECTRIC CO., New York City, N. Y., is installing private telephone systems for industrial plants. A recent installation was at the plant of the J. I. Chase company at Racine, Wis. This Company operates a large plant the main buildings of which are as much as a half a mile apart. Two private exchanges with switchboards have been installed and will be connected by trunk lines. Three thousand feet of 25-pair and 12,300 ft. of 50-pair cable will be installed. There will be outside distributing points on the grounds, at which cable terminals will be placed. Loud ringing bells will be placed at various points inside and outside of the buildings to call officials to the nearest telephone. These bells can also be used to sound alarms.

HAYDEN STONE & COMPANY wire assuring us that the announcement of the purchase of the Butte-Duluth mine by that firm is an error.

SMELTER fume litigation has caused annoyance and loss out of all proportion to its real importance. In the report of the Selby Smelter Commission, which we print this week, it is shown that the real difficulties are easily met when both sides co-operate to determine the exact facts. We congratulate all concerned on the findings of this Commission. It has set standards for others and has solved problems that were leading to endless bitterness and litigation. Incidentally we would call attention to the promptness with which the Selby Smelting & Lead Company adopted every suggestion made by the investigators and to the open-mindedness obtaining on each side.

HYDRAULICKING, once a great industry in California, was stopped by court injunction. Whether it can be revived or other means found for working the mines then closed is a large question discussed by Mr. C. S. Haley in the two articles of which we print the second this week. As a first step the United States Geological Survey and the Bureau of Mines are to undertake a comprehensive investigation of placers and placer mining in the United States. In this work Mr. James M. Hill will represent the Survey and Mr. Charles Janin the Bureau. Mr. Hill will investigate the geological problems involved, and Mr. Janin, those relating to mining. The studies will necessarily extend over two or more years, and will, we are sure, constitute a basis for much constructive work.

COPPER men are making strong efforts to induce the Department of State to assume a more aggressive attitude in the matter of detention by the British of shipments to neutral countries. A number of Western governors have appointed representative men to visit Washington and to impress upon the officials there the fact that this interference is producing conditions of such seriousness as to constitute a public danger in numerous districts in the West. Late in November Mr. Thomas T. Read, associate editor of the *Press*, had a long conference regarding the matter with the acting Secretary of State, Mr. Robert Lansing. It was expected then that negotiations with Great Britain would remove all difficulties within a few days. Steamship and insurance men, however, have not yet received such assurance as would clear the way for unrestricted shipments. On Wednesday last the Secretary of State, Mr. W. J. Bryan wired Mr. Read as follows: *"Department making every effort to relieve copper situation. Exact meaning of articles covering copper now on contraband list is being obtained from Great Britain preparatory to further discussion of the subject."* Our readers will be glad to know that the matter is receiving earnest attention and that the Department of State hopes soon to have cleared away the remaining obstacles.

FOREIGN capital invested in South American mines does not always mean European money. Chileans own or control a surprisingly large number of mines in Bolivia. The Patiño mines, which produce about one-third of the Bolivian tin, are locally owned, but the two next in size, the Llagua and the Oruro, are Chilean owned, though managed in the one case by American engineers, and in the other by a Hollander. Many of the smaller tin mines are also Chilean owned. The Aramayo Francke is British owned, as are many of the nitrate mines in Chile, the remainder being controlled locally, as are the coal mines. At Corocoro, the two principal copper properties are owned by Chileans and Frenchmen respectively. The French also own the Naltagua, Catemú, and other properties in northern Chile. The Braden, Chuquicamata, and Cerro de Paseo, which overshadow all others in size, are controlled in the United States. In Peru the Backus & Johnston interests, the second most important in copper, are under Peruvian control. The Bethlehem Steel Corporation, as is well known, has recently leased from the French, important iron mines in Chile, and, on the whole, the big properties on the west coast are less generally under European control than is usually supposed.

ENGINEERS and metallurgists in the copper country of the Lake Superior region have been notably chary of writing and publishing of recent years. This is all the more a pity since the region is one of much technical interest and the men working there are among the best in the profession. It is said that the general blanket of silence has been due to an unfortunate experience of one of the companies with an Eastern technical journal. That is ancient history of which we do not profess to

have direct knowledge. What is more to the point is the fact that the old spirit is passing. In the excellent address upon the work of the safety department of the Calumet & Hecla, of which we print a part this week, Mr. Bailey not only reveals the cheerful helpful spirit that any visitor to the region feels, but he gives detailed facts of wide value. Other papers are in store. Incidentally, we note with regret that our Chicago contemporary, *Mining and Engineering World,* printed December 12 the report of the Selby Smelter Commission, of which identical copies were sent to all the technical journals with a release date of December 17. It is such things that make trouble.

IN an interesting and valuable article on 'Zinc and British Trade,' published in the November issue of *The Mining Magazine*, Mr. H. M. Ridge makes the statement "The silicate of zinc, which in the trade is included under calamine, although in mineralogy it is known as smithsonite * * *" Many American readers will have regarded this as a slip of the pen, and continued their perusal of his significant remarks. Actually, however, the sentence is not a slip of the pen, but an illustration of the difference between the American and the British languages, which are collectively called English. From the earliest historic times there seems to have existed some confusion as to the ores of zinc, and even after scientific mineralogy was well developed, miners and mineralogists failed to distinguish between the carbonate and the silicate of the metal, which look much alike and often occur together, calling both calamine. It was left to James Smithson, best known to Americans as the founder of the Smithsonian Institution at Washington, to point out that two different minerals were covered by the one name. Through some perversity of chance the name of smithsonite was attached to the silicate by English miners and mineralogists, while it was in America used to designate the carbonate, the name of calamine continuing to be used in both countries to designate, in a vague way, either or both. Thus the confusion still persists, though a British and American engineer may to some degree relieve it by remembering that when his cousin speaks of the one mineral he really means the other.

MAGNESITE

Magnesite is one of the substances on which public attention has been focused by the war in Europe, which for a time interrupted our supply, since the domestic output constituted less than 10 per cent of the $1,500,000 worth of magnesite which is consumed in this country each year. It is used for a variety of purposes, the best known being the making of fire brick and other refractories and for the linings of reverberatory furnaces, chiefly for the making of steel. For this purpose it is first dead-burned, or calcined down to a CO_2 content of less than 1 per cent, in which condition it does not reabsorb CO_2 and moisture from the air. To be satisfactory for this purpose, it must be low in lime, silica, alumina, and iron oxide, though it must be added that it does not seem difficult to find material which is pure enough to be satisfactory for this purpose. Another well known use is for making coverings for steam pipes, so familiar to all. Of less present but apparently much greater future importance are the cement mixtures which are just beginning to attract attention through their use as flooring in bathrooms, hospitals, and other places where a sanitary, waterproof, wear-resisting and warm floor covering is required. In the construction of the buildings for the Panama-Pacific International Exposition a considerable local demand for this purpose has been created, and the output of magnesite in California has largely increased for this reason. Caustic magnesia, the name by which magnesite is known when it has been calcined until its CO_2 content is reduced to 3 or 4 per cent, has also proved recently to be of much value in the bisulphite paper pulp industry, since it seems to be more satisfactory for this purpose than calcium bisulphite and is much cheaper than sodium bisulphite. At one time crude magnesite was used in the soda water industry as a source of CO_2 gas, but in order that its use for this purpose should be more economical than the use of limestone, it is necessary to find a market for the magnesium salts thus produced, and this is increasingly hard to do.

Magnesite deposits occur rather widely, as might be expected, since magnesium is about as abundant in nature as calcium. The massive deposits occurring on the island of Euboea, in Greece, are among the best known and have been worked for many years. It here occurs in thick lenses in serpentine, and as it is not far from the seacoast, in a country where labor costs are low, it can be placed on shipboard at a low cost. Important deposits of crystalline magnesite occur near Salzburg in Austria, and extend across Styria and Hungary to near the Russian border. These deposits are very pure and have been extensively worked for that reason. Practically all the magnesite brought to this country is from one of these places or from Greece.

When the war first broke out, the prospect of a total cutting off of the Austrian supply and a possible interruption in shipments generally, caused the price of magnesite to rise rapidly, but since shipments from Mediterranean ports are now free from interruption the Grecian deposits have risen to the situation, and it is reported that the latest shipload of magnesite received in New York was contracted for at a price only $1 per ton above the prices prevailing in July. The horizon is not entirely clear yet, however, for it is not without the bounds of possibility that Greece will also be drawn into the war, when European supplies will be entirely cut off.

Magnesite occurs at a number of points in California and a growing industry is developing. The principal occurrences are in the Coast range, though in the foothills of the Sierras, in veins in serpentine, magnesite is also found. It is mined in Tulare, Fresno, Kern, Placer,

Riverside, San Benito, Santa Clara, Sonoma, and Napa counties, and the calcined product sells for from $10 to $25 per ton. California operators are hopeful of building up a permanent trade as one result of the war.

SMELTING IN COLORADO

An interesting contribution to the history of the development of smelting operations in Colorado was made by Mr. H. W. Hardinge at the November meeting of the New York section of the American Institute of Mining Engineers. Dr. James Douglas, the chief speaker of the meeting, had recalled the important advances made by the pioneers of smelting in Colorado, at Black Hawk and Argo. Mr. Hardinge then brought out the interesting fact that the development of smelting in Colorado owed a debt to Dr. Douglas of which he was unaware. About the close of 1890, Mr. Hardinge was manager of the smelting plant of the Arkansas Valley Smelting Company at Leadville. The silver content of the charge was so high and the lead content was so low that the slags being made averaged three to four ounces silver per ton, at a time when silver was worth over a dollar an ounce. Dr. Douglas visited the smelter one day and, noting this fact, casually remarked that the addition of a small amount of copper to the charge would clear the slag of silver. The suggestion was at once tried by Mr. Herman Keller, the superintendent, who had previously made some experiments along the same line himself, and one-half per cent of copper in the form of copper ore was added to the smelting charge, with the gratifying result that the slag decreased to 0.93 ounce silver per ton for the monthly average. Later the accumulated slag was re-smelted at a good profit, its silver content being recovered and its good iron content allowing the simultaneous handling of silicious ores at a correspondingly high smelting charge. Within a short time the practice became general throughout the state, and the shipping of lead mattes to eastern refineries for treatment at a high penalty was discontinued. Thus a casual remark was instrumental in fundamentally altering smelting practice in a whole state.

An interesting incident connected with this development is that a fellow metallurgist refused to believe in the results attained, stoutly maintaining that the smelting of copper and lead in the same furnace was a physical impossibility, and was only convinced by being shown the checks received in payment for the products made. Dr. Douglas had earlier in the evening related that when one of the most distinguished metallurgists of the day first heard of the use of water jackets in copper smelting he asserted that the thing was an impossibility, that sulphide ore could not possibly be smelted in contact with iron jackets without bringing about their destruction. The moral drawn by Dr. Douglas was that it is scarcely safe to assert that anything is impossible; and he concluded by asserting his belief that the ideal metallurgical plant of the future will be constructed of scantling, so that it can be easily taken down in making the inevitable changes in practice which careful study never fails to bring about.

INSURANCE RATES TUMBLE

Last January a new workmen's compensation act went into effect in California. In applying the general principle that each industry should carry its own burden of cost of accidents, many new provisions were made and a system was established that rendered inevitable a somewhat higher rate for insurance than that in other states. As we noted January 17, circumstances made it necessary for mine operators to deal with private insurance companies, and these, acting through a single board, established rates that were absurdly high. Specifically, mine operators were asked to accept a basal rate of 7.86 in gold mining and 9.80 in iron and miscellaneous mines. Questioned regarding this the companies maintained that these rates were based upon mining experience in Massachusetts and New Jersey; which carried its own answer to Western mining men. We are sure that the owners of the Davis pyrite mine in the one state, and of the Franklin Furnace zinc mine of the other, if asked, would have disclaimed fixing an insurance rate for California gold mines, but the faith of an insurance man in a few figures is absolute—when they are his figures.

Naturally a vigorous protest was made, and in that we had the pleasure of taking part. With records and data supplied by mining men in and outside the state, we took the matter to the Industrial Accident Commission, meeting there a wholly sympathetic attitude and finding there a cordial spirit of co-operation. Various efforts at amelioration of conditions have been made, as we have noted editorially, particularly in our issue of July 11, there has been some rate cutting, and various proposals have been made and rejected. The final result can now be announced. Negotiations between Mr. Fellows on behalf of the Industrial Accident Commission and the Workmen's Compensation Bureau, which fixes rates for the so-called 'board' companies, have led to establishment of the following rates for 1915: underground men, 5; dredge men, 4.8; mill men, 2.79. Furthermore, the Industrial Accident Commission, acting through the state insurance fund, will accept unlimited mining risks. At a recent conference between the Commission and mine operators, Mr. Albert Burch estimated on the basis of Nevada experience, that the California rate should be 5 per cent, and we are greatly pleased to see that the Commission has found it possible to meet the wishes of mining men fully in this particular. We hope that care and attention may so decrease the number of accidents as to permit a steady reduction in the insurance rate. We do not look upon 5 per cent as low. One large company carrying its own risk from a special fund levied at that rate, and with apparently a normal number of accidents, is building a surplus rapidly. With safer mines, and workmen and superintendents more keenly alert to prevent accidents, it should be possible to operate at a much lower rate.

LOOKING FORWARD

Speaking before the Copper Country Michigan College of Mines Club last week, Mr. O. F. Bailey told of the 'Safety First' work inaugurated in the Calumet & Hecla mines by Mr. James B. McNaughton on the basis that it was "better to reduce the number of accidents than to send flowers after they had happened." Mr. Bailey explained that after a period of careful recording and studying of accidents as they took place, and of interesting the foremen in the work, 'Safety Committees' were just about to be organized when the labor troubles of 1913 delayed the whole matter. A year later these committees were organized, and they are now at work. Mr. Bailey said further:

"We have 37 department committees consisting of 190 members. These are picked from the workmen and they are appointed to serve a period of from two to six months. For example, the Osceola Consolidated company has four department committees, three underground of from five to six men each, and one surface committee consisting of five members. An underground committee is usually composed of a boss, a miner, a timberman, a shaft-man, a trammer or laborer, and in some cases an efficiency engineer. The surface committee is made up as a general thing of a boss, a carpenter, a blacksmith, a machinist, and a laborer. The intention is to have each and every occupation represented. The object in this is to encourage men from all of these occupations to call attention to unsafe conditions or methods, and we figure that it is easier for them to do this with one of their own number.

"Each department safety committee is scheduled to make a trip of inspection twice each month, making a minimum of four trips for each committee. These trips usually consume half a day, the remainder of the day being given over to discussion of what they find and in making a report and recommendations to the general committee. A department committee does not make all of its trips through the same mine; for instance, we try to arrange it so that the underground committee for the South Kearsarge will make two trips through the South Kearsarge mine, one trip through the North Kearsarge or Old Osceola, and still another trip through the Calumet & Hecla or some other. While making these inspection trips each member is expected to talk with the men working underground, especially those of his own occupation, and explain to them the object of the committee and to secure such information and suggestions as he can as to improvements in conditions or methods, which may result in the prevention of accidents. The members of these committees are paid full time and actual expenses while engaged in this work. We have had a few cases where the report was to the effect that they found everything in perfect condition, but most of them have taken the matter seriously.

"I have picked out one report which will give you an idea of what we are receiving.—'The Committee recommends: That the loose ground just below the 48th level be taken down; That the hanging be laced up on the 69th level north and the 70th level north, to make it safe for the trammers, and that stumps be placed in these two levels to keep up the back of the level; That the 71st level north be timbered up before any more ground is taken out and that a large piece of loose ground on the south end of the stope be taken down: Our Committee's attention was called to the fact that Joseph Boggio's timber crowd was without necessary tools for the safe conduct of their work and we recommend that he be furnished with axes, saws, chains, hammers, and snatch-blocks. We further recommend that the timber crowd of John Curto's be supplied with three-quarter inch rope.'

"Altogether we have twelve general committees, consisting of 80 members. These general committees are permanent, that is, the same positions are represented on the committee at all times, and in most cases the chairman of a general committee is also a member of the central safety committee. For example, the superintendent of the Ahmeek mine is chairman of the general committee for that mine and he has associated with him on the committee, the master mechanic, mining captain, and surface foreman. These general committees meet monthly. They read the reports and recommendations from the department committees and take action upon such matters as come within the authority of the members of the committee, and at the same time they make a report and recommendations to the central safety committee, and include in their report matters reported by the department committees.

"When new members are appointed on department committees it has been our custom to get seven or eight committees together at one point and outline the plan to them, giving them assurance that their report on conditions and their recommendations are solicited and disabuse their minds of any feeling that they are sent out to find fault with their boss or for the purpose of getting anyone into trouble. At the time these committees are appointed, every member is furnished with a 'safety button.' Another thing which we are now doing to bring the members of the safety committees, as well as other employees, closer together in this matter is the provision now being made for an assembly room at Calumet which will hold from 75 to 100 men where we can get them together and in addition to talking to them of our plans expect to give them a chance to be heard on this subject.

"I hope some day in the near future that we will be able to publish an Employees' Magazine for the Calumet & Hecla and subsidiaries. In addition to safety matters, it would be my idea to include items of general interest in our business as well as items of local interest, and I look upon it as a means of giving employees, as well as the general public, a better idea of what we hope to accomplish."

A Plan for Reviving Hydraulic Mining—II

By C. S. HALEY

In restraining the operations of hydraulic mining, the need of a training in the principles of the industry would seem to be as necessary as in the actual operation of the mines themselves. The building of satisfactory but economical dams, the recognition of the principles controlling the transportation of débris by running water, and the percentage of sand and clay, as well as light cobbles, in the gravel being worked, should all be taken into account. The natural erosion caused by the flow of streams under ordinary conditions is also a factor whose burden at present rests altogether on the hydraulic miner.

DÉBRIS DAM ON BEAR RIVER, CALIFORNIA.

Furthermore, the work requires all the time that can be given to it by a special body of men, if arbitrary restrictions are to be removed and a proper rate of production maintained. Under present conditions this is impossible. There is absolutely no reason why several times the present number of mines in the counties of Nevada, Sierra, Placer, and Plumas, as well as other counties to the south, should not be in active operation today, as far as the damage done by débris is concerned, except that regulation is not only exceedingly arbitrary, but intermittent. It really is easier, and pays better, in the more out-of-the-way places, to operate without a license than, by seeking to do so in a lawful way, to advertise the fact that you are working. More than one instance can be named of a legitimate operator being forced to bear the blame for the muddying of the rivers when the damage was actually done by another person on the same stream who was working intermittently and illegally. Is it any wonder that, under such conditions, operators who are acting in entire good faith, and in accordance with the law, become disgusted and close down their properties?

The photograph above is that of a dam on Bear river. It was built by two mining companies, one of which was later enjoined, while the other was permitted to work unrestricted. Later, permission was given to a third to hydraulic further up the river at a time when no settling pool remained at this dam. All of which goes to show the necessity of placing the regulation of hydraulic mining in the hands of a body of experienced men whose sole business it is to attend to it.

Another point which has tended to cut down hydraulic

production has been the increasing use of water for power and irrigation purposes, as well as its use for domestic supply in various towns. Recently in Auburn, the very town in which, 23 years ago, the movement to rehabilitate hydraulic mining began, a protest was filed against the muddying of the American river. Such protests, considering the condition of the river during about half the year in flood time, seem rather unnecessary. The use of a modern filter would be far more effective.

On the other hand, there is no question but that the power interests have grown to a position of great importance, as well as have the irrigation systems. Nevertheless, there is here no need for conflict. During from four to six months of the year the streams of the Sierras carry an excess volume of water which all the dams and storage systems yet devised, or that are likely to be devised during the next few centuries, cannot contain. This water, or a small portion of it, is what the miners would use, and during slack water they would be willing to shut down.

Such, then, are the conditions that confront the hydraulic miner today. The remedy for this state of affairs is simple, and should be applied, as it means the increasing of California's gold production from one to two millions of dollars annually, and the restoration of a portion of its former wealth to that portion of the commonwealth which was at one time its mainstay, its pride, and the source of its present prosperity.

Yuba River Discharge

In a recent publication of the United States Geological Survey, entitled 'The Transportation of Débris by Running Water,' the distinguished author, Grove Carl Gilbert, makes some very interesting statements. In speaking of the flow of the Yuba river and its suspended load, in 1879 when that stream was at its flood and hydraulic mining was being carried on, the following results were noted: When the discharge was 26,000 cu. ft. per second, a load of 0.35% by weight was noted; when discharge was 18,000 cu. ft., the load was 0.42%. At low water in the same year, when discharge was 510 sec.-ft., a load of 0.86% was noted. The fact that the river's load is greater in proportion during low water is explained by the fact that the turbid tributaries of the river are less diluted with the clearer water from other tributaries. From these results, it will be noted that a decrease of 97% in volume brought about an increase of virtually 150% in the proportionate load.

On the other hand, in 1906, when most of the hydraulic mining was suspended, with a discharge of 33,000 ft., the load was 0.065%. If the increase in load is at all regular for large volumes (which appears a warrantable assumption), the suspended load for a volume of 18,000 ft., the same as in 1879, would have been about 0.13%, or about one-third of what it was at the time when the hydraulic mines were working at capacity. In other words, the volume of débris carried down by natural erosion is, when the mines are mostly shut down, about one-third as much as when they were working full blast. As conditions of stream bed and other factors were in 1879 more favorable to débris suspension than in 1906, it may be assumed that this factor is low rather than high.

The fact that at low water the percentage of débris transported is so much less than it might be calculated to be is, of course, explained by the deposition of débris by the feebler currents, and consequent shoaling of the river.

Débris Deposited in Streams

Returning again to official statements, I find the following in the report of the Débris Commissioner, from May 1901 to December 1902:

"The débris flow has caused the destruction of thousands of acres of fertile farms and the serious impairment of navigable rivers. Its attempted solution by injunctions by the courts has resulted in the destruction of a profitable industry of the state—that of hydraulic mining. Although many reports have been made on the subject, there are certain features that have not been given due weight, because the various investigators were not in touch with the actual conditions leading to the débris flow. It is this lack of knowledge that has in a great measure retarded its solution in the past. Careful consideration by those most interested will show that there is common ground to stand on, and it is hoped that it will lead to a 'community of interests' that is so necessary to hasten the much-needed work. * *

"The California Débris Commission in 1894, from the result of borings made by Col. W. H. Heuer, placed the amount of débris from Marysville to Daguerre Point, a distance of 9½ miles, at 308,000,000 cu. yd., and estimated 100,000,000 cu. yd. more to the Smartsville dumps, or a total of 408,000,000 cu. yd. I am of the opinion * * * 600,000,000 cu. yd. are deposited within this area. Of this amount there were deposited * * * during the period 1879-1899, * * * a total of 100,550,000 cu. yd. This represents the cleaning of the cañons, the washings of the hydraulic and other mines, and from natural causes.

"During the past eight years, I have endeavored to determine what the relative erosion was on Deer creek. * * * In the years gone by there was, in this watershed, considerable hydraulic mining, which is now practically abandoned. The dumps have been so cut and carried away as not to affect the winter flow. Altogether it can fairly be considered average conditions for natural erosion on the watershed. On January 3 and 4, 1895, there fell 7.08 in. of rain in 23½ hours. The creek was very high and muddy. The percentage of silt was determined and a rough gaging of the flow made. After making liberal deductions for safety, it was found that the creek carried 86,000 cu. yd. of material past the town in 24 hours. Two-thirds of this, by weight, may be counted as sand, being the mean of a number of observations and checked by comparison of the composition of soils. At that time the Excelsior Water & Mining Co. was hydraulicking at Smartsville,

impounding the débris in a worked-out pit. It is one of the largest concerns operating under the California Débris Commission. Yet that storm sent down more material in one day than the Excelsior company mined in six weeks—boulders, cobble, gravel, sand, and 'slickens.'"

Miner Must Restrain Natural Débris

The point that I wish to make and to emphasize is that under the present system of building restraining dams and allowing operation until they are filled up, the gravel miner is forced to take upon himself the burden of restraining the natural erosion of the elements—a burden which, besides being absolutely unfair to him, is too titanic in its proportions to be borne by one class or industry alone.

By a study of the maps of the United States Geological Survey, the principal Tertiary gravels of the state will be found to be in the counties of Nevada, Plumas, Sierra, and Placer. Eldorado, Amador, and Calaveras, as well as Tuolumne and others, contain but small quantities of gravel compared to the immense bodies of the Alta, Gold Run, and Red Dog channels, and others around Dutch Flat and Nevada City.

During the early days of the industry, work was mainly confined to the lighter, surface gravels, and it is from these that most of the débris has come. The gravel which it is desired to work at the present day is as a whole much heavier in character, with the possible exception of isolated bodies such as that at You Bet. Of gravel of this type, where dumping is not done directly in the rivers, but upon bars adjacent to them, it may be safely assumed that from 75 to 80% of the entire material stays on the original dump or within a few hundred feet therefrom. The finer material and the sand, of course, goes down to the river, with the exception of what settles between the boulders of the dump. For this reason, it may be made as a fairly general statement, covering at least three-fourths of the Pliocene channels in California at the present day, that not more than 15% of the washed material will come within the field of the restraining dams.

Financing Reclamation Work

This being the case, it would seem that the matter of restraining this material from the rivers down in the valley should be fairly simple. A gravel tax would be cheerfully borne by the miners if they were allowed to have a fair chance to operate, and the revenue could be applied to the building and maintenance of restraining works in the principal river channels. This tax should in all fairness be regulated according to the relative fineness of the material being worked, thus throwing the burden of maintenance more heavily upon operators who produced the more débris. This tax being a yardage tax, would also not bear too heavily upon the small operators. Further, it would have the effect of eliminating all the operators who, by reason of the poor quality of their gravel, or its excessive fineness, could not afford to pay the tax. In this way a more real restraint would be put upon the quantity of débris than by all the engineering works that could be constructed.

Another point can here be readily made which illustrates again the principle of community of interest. Of late years the destruction of valuable farming land by gold dredging operations has been the subject of a good deal of comment, and most of the larger dredging companies in California at present live in a fear that public sentiment may cause them to close down their operations in the near future. In Australia, the necessity of reclaiming the damaged lands has long been recognized, with the result that in farming communities the gold dredges are forced, at considerable expense, to reclaim their land behind them by pumping the sand and silt back on top of the boulder piles. In the report of the Secretary for Mines, Victoria, series 1907 to 1913, detailed descriptions of the methods adopted, accompanied with photographs, are given. The expense involved in reclaiming is borne by the dredging companies, and, notwithstanding the value of the reclaimed land, cuts into profits enormously. Naturally, the American companies have been loath to follow their example. Nevertheless, the time is not far distant when the alternative of reclaiming the lands or closing down is apt to be forced upon them by some zealous legislature, anxious for re-election.

Reclaiming Dredge Tailing

As everybody who has been in the dredge fields knows, the uneven and irregular gravel heaps can be leveled, though at considerable expense. But getting a top soil upon them is another matter. It requires the use of suction pumps to bring up the sand and silt from the river beds. And just here is where the hydraulic miner could step in, to both his own advantage and that of the dredge companies. A few suction dredges, stationed in such places as on the Yuba river near Hammonton, on the Feather river below Oroville, and other similar localities, could handle all the material that the mines could dislodge from their now coarse gravel, aside from the use of restraining dams. The maintenance of these dredges could be paid out of a fund created by a gravel tax levied as suggested, and the dredge companies could co-operate. The cry of forty years ago was, 'Too much sand and silt'; that of today seems to have been reversed, in the case of the dredgers.

To carry out any readjustments of the problem of débris control, certain radical changes would have to be made. In the first place, the whole problem should come under the direct control of the United States Bureau of Mines, which is now extending its activities into the Western fields. The débris commission should be composed of engineers appointed by the Bureau of Mines, and a man of practical experience should be retained on the job as long as possible, as it is in his experience and length of service that his chief value would lie. One member of the commission should, of course, be an army officer, representing the river and harbor work. The others should be veteran mining engineers; there will be many capable men found retired from the most active

forms of the profession. Under them should be a body of younger engineers, whose chief duty should be to keep records of all work done, survey and engineer dams and restraining works, survey and keep contour maps from year to year of all operating properties, which maps would show from computation of dumps and worked out ground just how great a tax should be borne by individual companies and operators, and how much impounding space has been filled in by actual working, and not by natural erosion. This would not be complex, nor need it require a large corps of engineers, as with stadia and transit work; large areas could be gone over in a very short time, and the maps readily altered from year to year.

The adjustment and regulation of a gravel tax, to distribute the burden of restraining works and dredges, would of course require the judgment and training of a skilled engineer, with long experience in hydraulic mining. At first there would be difficulties and minor dissensions, but as time went on, certain regular criteria would gradually assume definite form, and the tax would be justly administered. The objection may be made that superior opportunities for corruption would be offered, but if the work were carried on by the government, it would be infinitely less open to such practice than when carried on under the auspices of such an organization as the once powerful Anti-Débris Association has come to be.

Advantages of Plan Proposed

The chief advantages of such a readjustment would be: (1) a definite understanding between the government and the hydraulic miners as to just where the latter stand—something which seems at present to be very vague; (2) a distribution of the burden of restraint which would be just and equitable; (3) the elimination of natural erosion from the question and the removal of the prohibitive tax which it now imposes on the industry; (4) a part solution of the waste dredge lands problem, which is now vexing the state more and more; (5) the removal from the shoulders of the officers involved in the river and harbor work, a burden they would thankfully be rid of, and its administration in more experienced and qualified hands, not subject to frequent change.

And the greatest advantage of all would be the immediate resumption of hydraulic mining on a scale which would once more be worthy of the commonwealth which the industry has helped so much to create. There is no question but that the gold production of California could readily be increased from two to three millions a year, if the owners of hydraulic mines could once be assured of their rights under the law, and not under the very dubious judgment of a body of men who have but little time to devote to the subject, and who receive no compensation for the time which they do devote to it. The effect of the change would be astonishing and instantaneous among the mining men of the state.

In conclusion, then, the whole matter resolves itself in this way. An act of Congress will be required to repeal the Caminetti act and to place the whole question under the jurisdiction of the Bureau of Mines. The latter has already, in the course of the few years of its existence, shown itself capable of dealing promptly and efficiently with many problems wider in scope and more involved in detail than is that of the rehabilitation of hydraulic mining in California. This being the case, should it favor such legislation its enactment by Congress should be easy to obtain.

Having assumed control of the situation, a commission somewhat along the lines suggested could take charge of the entire matter and work out the details of a plan which would be at once satisfactory to the miners and not prejudicial to the agricultural interests. There is plenty of common ground to stand on, and the attitude of the miners can hardly be surpassed in liberality by the farmers. The resumption of hydraulic mining on its former scale is, of course, not to be expected; but the half billion to a billion of dollars that is at present absolutely locked up in useless ground of the Sierra Nevada may well be expected to be in time added to the riches of the commonwealth of California in increasing volume as time goes on and the efficiency of a practical working plan of control is demonstrated.

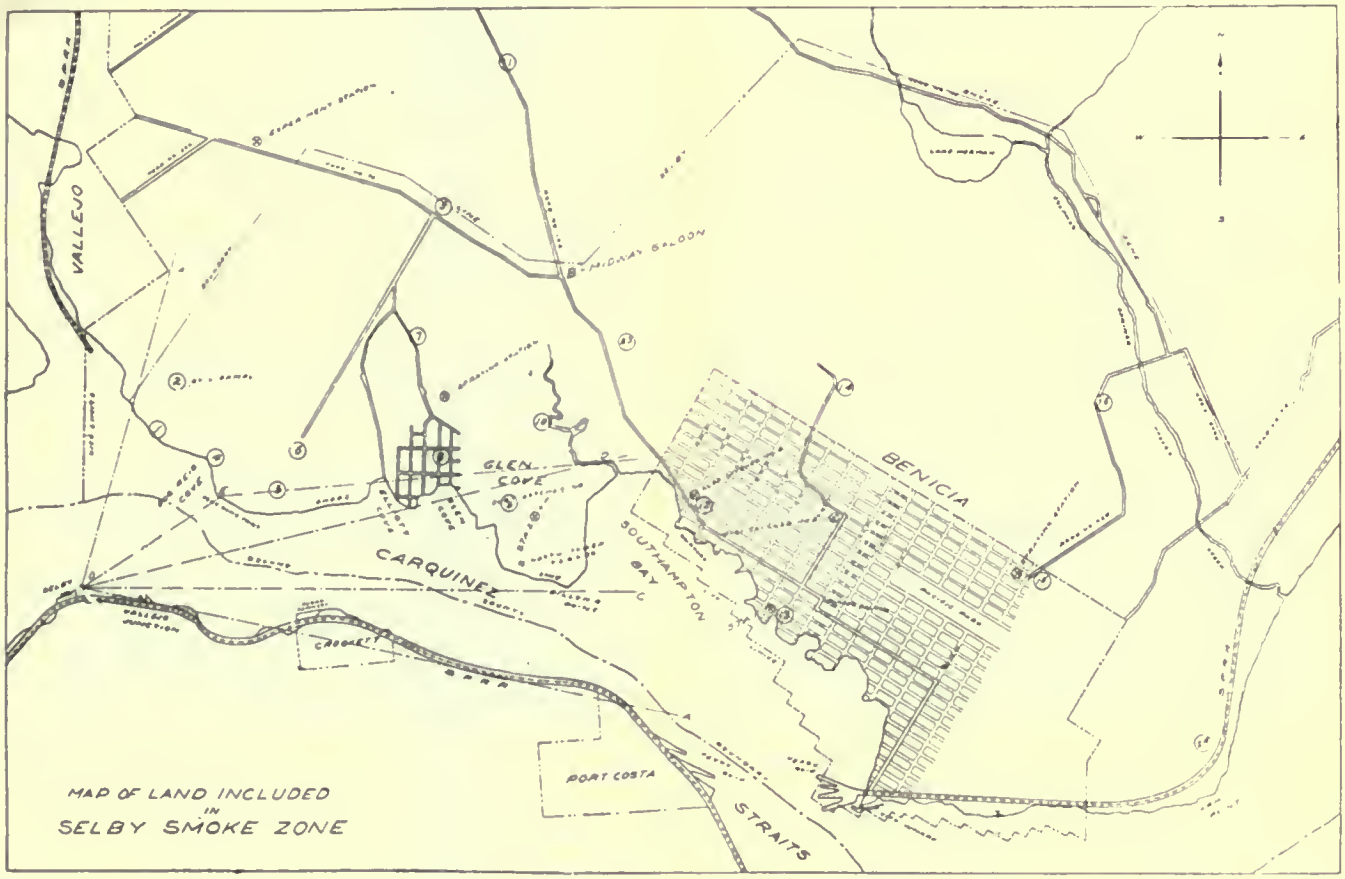
The result of the whole thing would in a very few years mean the building up of a now partly impoverished and retrograded district in the eastern part of the state, the employment of a considerable army of useful men, and an increase of gold circulation which at the present time is very sadly needed. Shall we continue to talk about it, or shall we get some action?

The Transvaal being such a large gold producer, it is highly desirable that the mines be kept in operation during the war. At the quarterly meeting of the Chamber of Mines at Johannesburg, the president, E. A. Wallers, made the following statement: "At the commencement of the war, the matters of the supply of essential stores for the mining industry, and the disposal of our gold naturally claimed the very closest attention of the executive committee. It is with great pleasure that I am able to state that, with the efficient and sympathetic help of the government, both here and in London, every assistance has been given to the industry to enable us to insure the continued working of the mines. The arrangements made in regard to mining supplies are satisfactory, and there is little doubt that sufficient will come forward as required, although there may be a little temporary stringency at certain times, but nothing, as far as we can see, that should prevent us from carrying on operations at full blast. Most of the members of the Chamber have pooled their supplies of cyanide, mercury, and zinc, and have entered into joint contracts for the supply of these articles for an appreciable period. As regards the question of mining supplies in general, I might add that we have at various times met the representatives of the Chambers of Commerce and Trade, and their attitude throughout the whole matter has been extremely helpful."

Report of the Selby Smelter Commission

The filing of the report, findings, and recommendations of the Selby Smelter Commission with the Superior Court of Solano county settles finally and conclusively the long-continued controversy between the residents of Benicia and the adjacent agricultural country and the Selby Smelting & Lead Co. concerning the alleged disagreeable and injurious effects produced by the smoke from the Selby smelter.

The smelter operated by the Selby Smelting & Lead Co. is situated near Vallejo Junction in Contra Costa county, California, at the western end of the Carquinez straits. The city of Benicia is situated in Solano county at the eastern end of the straits, about five miles from the smelter. During nine months of the year the prevalent trade winds blow the smoke from the Selby smelter over and into the city of Benicia and the agricultural area lying between Benicia and Vallejo.



On March 14, 1905, action was brought by the district attorney of Solano county, California, in the Superior Court of Solano county, praying for an injunction which would restrain and enjoin the Selby Smelting & Lead Co. from permitting injurious smoke and gas from the Selby smelter to blow over and upon the city of Benicia and the tributary country. The case was brought to trial on August 7, 1906, and judgment of the court in favor of the plaintiff was rendered on July 16, 1908. The decree of the court was to the effect that during eight months of each year between March 15 and November 15, the Selby company was enjoined from discharging noxious gases and fumes into the open air in such a manner that the same would be carried into and upon the city of Benicia and the tributary country in Solano county in such quantities as to be offensive to the senses and to interfere with the comfortable enjoyment of life and property.

After motion for a new trial was made by the defendant and denied by the court, an appeal was thereupon taken to the Supreme Court of the state. On June 12, 1912, the judgment of the trial court was affirmed by the Supreme Court.

During the period covered by this litigation the Selby company had been making efforts toward the elimination of some of the objectionable constituents of the smoke, these efforts having resulted in the removal of the major portion of lead, arsenic, and sulphur trioxide from the smelter smoke. In the spring of 1913, although the Selby company maintained that it had abated the the nuisance, complaints were made by the residents of the area that a nuisance still existed, and that the decree of the court was, therefore, being violated by the smelting company.

Various considerations, among them the prospective heavy expense which would accrue to both parties to the litigation as a result of a trial of the smelter con-

pany for contempt of court, led to conferences of the attorneys representing both sides, which resulted in an agreement to submit the question of fact as to the violation of the decree of injunction to a board of technically trained men, deemed by both sides to be qualified to act in such a capacity, and equal financial responsibility of the parties in the expense of the commission's activities. The result of the agreement was the filing of a stipulation in the record of the cause providing for such a board. On May 22, 1913, this board was organized as the Selby Smelter Commission, with the following personnel: J. A. Holmes, director U. S. Bureau of Mines; E. C. Franklin (at the time of appointment chief of the chemical division of the Hygienic Laboratory of the U. S. Public Health Service), professor of organic chemistry, Leland Stanford, Jr., University; Ralph A. Gould, chemical engineer, San Francisco, secretary of the commission.

Facts to Be Determined

The function of the Selby Smelter Commission was to determine the facts and report its findings on the following:

1. Is the Selby smelter operating in such a manner as to violate the decree of the court dated July 16, 1908?

2. If the defendant company is violating the decree, what is the extent of the violation?

3. If the defendant company is violating the decree, what steps must be taken by the defendant to avoid a violation of the decree?

For the determination of facts, the commission and its staff have carried on careful and complete investigations of all matters which in the opinion of the commission could have any bearing on the questions at issue and to be answered. These investigations were made by the following staff of trained scientists and technical men, no one of whom otherwise than in arriving at the truth was directly or indirectly interested in the findings of the commission: A. E. Wells, metallurgist and chief chemist, in charge of smelter investigations and field work; C. B. Dutton, special legal agent, U. S. Bureau of Mines; Charles F. Shaw, professor of agronomy, College of Agriculture, University of California; E. E. Free, soil expert and agronomist; J. W. Blankinship, plant pathologist; Wyatt W. Jones, plant pathologist; R. W. Doane, professor of entomology, Leland Stanford, Jr., University; C. M. Haring, professor of veterinary science, College of Agriculture, University of California; K. F. Meyer, professor of bacteriology and protozoölogy, University of California.

Through the courtesy of Thomas Forsyth Hunt, dean of the College of Agriculture, and F. T. Gay, of the department of pathology, the commission had the valued co-operation of several of the staff of the University of California. The facilities of the U. S. Bureau of Mines also were placed at the disposal of the commission and much assistance was rendered by its staff of experts, especially F. G. Cottrell and L. H. Duschak.

The results of the investigations of the several experts were presented to the commission in the form of reports, as given below:

Results of Investigations

1. A Detailed Study of Statements of Residents of the Selby 'Smoke Zone' as regards the presence of a Nuisance in the Area, by C. B. Dutton.

2. Conditions in and around the Selby smelter and the Selby 'Smoke Zone,' by A. E. Wells.

3. Investigations to Determine the extent of the Contamination of the Atmosphere in the Selby 'Smoke Zone' by the Smelter Emanations, by A. E. Wells.

4. Investigations to Determine the Sulphur Dioxide present in the Atmosphere in places outside the Selby 'Smoke Zone,' by A. E. Wells.

5. Conditions of Plant Life in the Selby 'Smoke Zone,' by J. W. Blankinship.

6. The Occurrence of Sulphur Dioxide Injury to Plants in the Selby 'Smoke Zone,' by Wyatt W. Jones.

7. Insect Pests in the Selby 'Smoke Zone,' by R. W. Doane.

8. Agronomic and Soil Conditions in the Selby 'Smoke Zone,' by Charles F. Shaw.

9. Investigations of Live Stock Conditions and Losses in the Selby 'Smoke Zone,' by C. M. Haring and K. F. Meyer.

10. Fumigation Experiments to Determine the Effect of Highly Diluted Sulphur Dioxide upon a Growing Grain Crop, by A. E. Wells.

11. Investigations to Determine the Effects of Sulphur Dioxide on Man, by A. E. Wells.

12. The Possibility of Reducing the Sulphur Dioxide Output from the Selby Smelter—(*a*) Investigations on the Gases from the Dwight and Lloyd Sintering Machines of the Selby Smelter; (*b*) Studies in the Commercial Utilization of the Sulphur Dioxide produced by the Selby Smelter; by A. E. Wells.

13. Bibliography, 'The Effect of Sulphur Dioxide on Vegetation and Animal Life,' The Chemists' Club Library, New York.

The field investigations upon which these reports are based were conducted between June 1913 and September 1914.

Is There a Nuisance?

In collecting the data for his report, Mr. Dutton interviewed the residents of the 'smoke zone' in as thorough and as representative a manner as possible, and sought to obtain directly their ideas concerning the existence of a nuisance. The opinion expressed as to the existence of the nuisance and injury from the smelter smoke varied from the extreme of unreasoning radicalism to entire indifference.

A study of Mr. Dutton's report reveals the fact that two classes of odors have been described by the residents of the 'smoke zone' as 'smelter smoke;' one is undoubtedly that due to sulphur dioxide, and the other is that of certain products from the refining of petroleum, the so-called 'oil smell.' Judging from the statements of these residents, there can be no doubt that in the past, un-

til 1910 or 1911, there was present at times in the 'smoke zone' fumes and gases possessing very disagreeable odors, the 'oil smell,' which could not possibly have been due to smelter emanations. Subsequent to 1911, 'oil fumes' have not been so prevalent, but occasionally the odor of sulphur dioxide has been detected.

The conclusions derived from Mr. Dutton's report are that among the greater proportion of the residents there is at the present time only slight, if any, legitimate objection to the presence of 'smelter smoke' in the atmosphere of the 'smoke zone.' Under extremely unfavorable conditions and to supersensitive persons, 'smelter smoke' may occasionally be smelled in the area,

GASES FROM BLAST-FURNACE AND ROASTERS WITHOUT AND WITH CURRENT OF COTTRELL APPARATUS ON.

but to the fair minded person such occurrences do not prevent the enjoyment of life nor are they detrimental to the health of the community.

The commission considers that one of the most important phases of its investigations has been the direct determination by chemical analyses of the sulphur dioxide contained in the atmosphere of the 'smoke zone.' This work was conducted under the superintendence of A. E. Wells, with the assistance of eight trained chemists and six helpers, and is believed by the commission to be the most extensive and exhaustive of its kind heretofore.

For the determination of sulphur dioxide, a method has been developed which is believed to be by far the best yet used in work of this character, in that it combines in a most satisfactory manner those characteristics which permit 'instantaneous sampling,' rapidity of execution, easy field manipulation, and a high degree of accuracy. Concentrations of sulphur dioxide as low as 0.2 parts per million of air are rapidly and easily determined by the method as developed and finally adopted by the commission. For the essential features of the method, the commission is indebted to J. R. Marsden, chief chemist of the Selby smelter.

For making observations in the field, two permanent laboratories were established, where sulphur dioxide determinations were made at brief intervals daily, and an automobile was equipped as a portable laboratory, by means of which determinations were made in all parts of the Selby 'smoke zone,' as well as in many places outside the Selby 'smoke zone.' The field investigations to determine the sulphur dioxide content of the atmosphere in the Selby 'smoke zone' extended from September 17 to December 15, 1913, and from March 1 to April 15, 1914, during which time 4862 determinations were made. During the same period about 700 determinations were made in places outside the Selby 'smoke zone.'

During the entire course of the investigations, especial attention was given to the metallurgical processes going on at the smelter and the amount of sulphur dioxide eliminated from the smelter during the tests in the 'smoke zone' has been checked by the staff of the commission. Determinations were made when the wind conditions were the worst possible for the area, and when, at the request of the commission and under its supervision, the output of sulphur dioxide from the smelter was the highest possible. Other tests have been made with the smelter entirely closed down and with the wind conditions favorable and unfavorable to the 'smoke zone.' Every attempt has been made to obtain these data under all possible conditions, in order that maximum, average, and minimum figures might be obtained

as to the sulphur dioxide content of the atmosphere of the 'smoke zone.'

Atmospheric Content of SO_2

Of the total number of 'instantaneous' samples (4862) taken in the Selby 'smoke zone' during the period of field work, 75% contained less than 0.2 parts SO_2 per million of air; 86% contained less than 0.4 parts SO_2 per million; and over 97% contained less than 1 part SO_2 per million parts of air. Only 21 samples, or 0.43% of the total contained more than 2 parts SO_2, and no sample analyzed more than 7.1 parts SO_2 per million. The higher concentrations were found only when puffs of the smoke from the Selby smelter were drifted by a gentle breeze over the most exposed portions of the 'smoke zone,' and at no time did a concentration greater than 2 parts SO_2 per million persist for a continuous period of more than thirty minutes. The total time during the whole period of the commission's investigation that the concentration of sulphur dioxide was more than 2 parts per million at any part of the 'smoke zone' was 220 minutes, or 3 hours and 40 minutes. Only on six occasions was the concentration above 3 parts SO_2 per million, and the total time that the concentration was above that amount was 65 minutes. Within the city limits of Benicia itself, the maximum concentration of sulphur dioxide found was 2.4 parts per million, and only 22 out of the 2840 samples taken in this portion of the 'smoke zone' contained more than 1 part SO_2 per million.

In the business section of San Francisco during calm mornings, the concentration of sulphur dioxide was found to be as high as 1.8 parts SO_2 per million. Under brisk wind conditions as are prevalent during the late morning and early afternoon during the period of trade winds, the sulphur dioxide content was seldom over 0.2 parts SO_2 per million. On the ocean beach no determinable quantity of sulphur dioxide was found. In Oakland and Berkeley, of the 148 determinations made, none showed a concentration of sulphur dioxide higher than 1 part per million. One hundred and three determinations were also made in the vicinity of Richmond, which showed an average value of 1.1 parts SO_2 per million, and a maximum of 4.5 parts SO_2 per million. In Martinez and vicinity, 168 determinations were made. The average of these determinations was 0.23 parts SO_2 per million, and the maximum 1.7 parts SO_2 per million.

The results of these investigations show that, on the one hand, although the atmosphere of other areas investigated shows a higher constant concentration of sulphur dioxide that the Selby 'smoke zone,' the maximum concentrations within that zone, on the other hand, are higher than any of the other areas investigated. These higher concentrations, however, never persist for more than a few minutes.

What Constitutes a Nuisance

In order to determine whether the concentration of sulphur dioxide found in the 'smoke zone' could be considered sufficient cause for a nuisance complaint, or could be injurious to the health of people residing in the zone, it became necessary to study the effects of high dilutions of sulphur dioxide upon man and to determine the sensitiveness of various persons to the gas. The following is a brief summary of the results of these investigations:

Of the 60 subjects experimented upon, 32 of whom were previously acquainted with the gas, no one was able to detect the presence of 1 part SO_2 per million of air. With concentrations of 2 parts SO_2 per million, several of the subjects detected the presence of something foreign in the air, but could not identify it, and two identified the gas by taste. With concentrations of 3 parts SO_2 per million, the greater proportion of the subjects acquainted with the gas were able to identify it, and at 4 parts practically all were able to do so. The greater proportion of the subjects not previously acquainted with sulphur dioxide did not identify the gas until the concentration was greater than 4 parts per million. In the investigations to determine what concentration of sulphur dioxide would be considered a nuisance to all persons, very little agreement was found between the ideas expressed as to what was a nuisance. As a general statement, it may be said that concentrations of 3, 4, and 5 parts SO_2 per million were not considered to be a nuisance even if continued for considerable periods of time; concentrations of from 5 to 10 parts SO_2 per million, if continued for 10 to 15 minutes, would be considered a nuisance; concentrations above 10 parts SO_2 per million, if existing for only a few minutes, would certainly be called a nuisance. It was definitely determined that concentrations below that at which the sulphur dioxide can be smelled, that is, below about 3 parts SO_2 per million, cannot possibly be considered a nuisance or cause for discomfort.

SO_2 in Air at Benicia

It will be recalled that in the atmosphere of the city of Benicia the sulphur dioxide concentration never reached 2.5 parts per million during the whole period of the commission's investigations, and that at one of the most exposed spots in the 'smoke zone' there were but six short periods when it was above 3 parts, reaching a maximum of 7 parts on one occasion only. In view of the established facts therefore, it is quite impossible to maintain that during the period of investigations by the commission the residents of the city of Benicia or of any other part of the 'smoke zone' have been subjected to a nuisance as the result of discharge of sulphur dioxide from the Selby smelter.

Extended experiments were conducted to determine whether such concentrations of sulphur dioxide as are found in the Selby 'smoke zone' are capable of doing any injury to crops or other vegetation growing in the zone. The plan of these experiments was to allow barley plants to grow normally in an open field, and occasionally and for definite periods of time to subject the plants to definite concentrations of sulphur dioxide. These experiments were carried out with the following object in

mind: (1) to determine the visible injury produced by definite concentrations of sulphur dioxide applied for definite periods of time; (2) to determine the economic injury or decrease in yield resulting from the visible injury produced; (3) to determine the possibility of 'invisible injury' to a growing grain crop and the extent to which this may take place.

Crop Experiments

In a field of growing barley, experimental plots 4 ft. by 20 ft. in area were laid out, and covered during periods of fumigation with a cabinet designed so as to interfere as little as possible with the illumination of the plot. The sulphur dioxide air mixture was blown in at one end and allowed to escape at the other, in such a way as to maintain a steady stream of air containing sulphur dioxide through the cabinet during the fumigation periods. The length of time of each fumigation varied between two minutes and one hour. Experiments were carried on simultaneously on a farm near Vallejo and at the University farm at Davis. At Vallejo, 106 plots, and at Davis 35 plots were experimented upon, with results which were concordant in every respect.

A concentration of 5 parts sulphur dioxide applied for an hour under ordinary humidity conditions produced considerable visible injury. Visible injury is produced on growing barley by concentrations of 1 part SO_2 per million of air if the length of time of application is sufficiently great. Thus, three fumigations of seven hours each produced slight visible injury and no reduction in yield, with air containing 1 part sulphur dioxide per million. Sixty-two fumigations of one hour each, with 0.5 parts SO_2 per million, irregularly continued through the growing period, produced very slight visible injury and no reduction in yield.

From a study of the results of these experiments in connection with the information gained from the investigations upon the sulphur dioxide content of the atmosphere of the 'smoke zone,' the commission has found that from time to time conditions may arise under which slight visible injury will be visited upon susceptible plants growing on the more exposed portions of the 'smoke zone.' Since, however, plants will endure a considerable amount of visible injury without any diminution of crop yield, the commission concludes that within the 'smoke zone' no economic damage results from the smoke of the Selby smelter. This conclusion receives convincing confirmation from the observations of the commission's plant pathologists, who have found no indications whatever of economic sulphur dioxide damage within the area of the 'smoke zone.' It was found that when the plants were at one time badly bleached, this fact did not necessarily mean a decrease in the yield. A number of plots badly bleached in the early stages of growth were observed to recover rapidly, and it was found that their yield at maturity averaged within three per cent of the yield from the check plots. Short time fumigations repeated a great many times, and of sufficient intensity to keep the foliage bleached throughout the season, were much more effective in reducing the yield than were one or two very strong fumigations.

No economic damage or loss as expressed in decreased yield of crops or decrease in the fertility of the seed resulted from the treatment of barley plants with quantities of sulphur dioxide insufficient to produce marked visible injury. Thus, there was no indication of an economic 'invisible injury.'

For the determination of the condition existing in the 'smoke zone' as regards the crops of various kinds and the many kinds of plant life found therein, the commission engaged two plant pathologists of a high degree of training and of extensive experience in the study of plants in relation to smelter smoke injury. Each was commissioned to make a complete plant pathological survey of the area, reporting all abnormal conditions which exist and to trace, wherever possible, the actual cause of such conditions. The only conclusions which can be drawn from the work done in the plant pathological survey are that such poor conditions of plant growth as exist in the 'smoke zone' are directly traceable to one or more of the following causes: plant diseases, predatious insects, poor soil, poor cultivation, lack of water, and indifference to all of these conditions by the farmers of the area. None of the conditions existing so far as vegetation is concerned can be attributed to the effects of the smoke from the Selby smelters.

From a consideration of the data collected during the entomological survey, the general conclusion reached is that lack of cultivation, lack of proper pruning, absence of spraying and fumigation with insecticides, are mainly responsible for the unusually bad condition which exists among the trees, vines, and shrubs in the Selby 'smoke zone.' The indifference of certain farmers to these conditions is illustrated by the fact that during his investigations, Mr. Doane volunteered to advise the farmers free of charge as to the proper methods of combating insects and to supervise their attempts, yet none of them accepted his services.

Poor Soil Means Poor Crops

The problems presented to the agronomic soil experts were: (1) Are the agronomic conditions of the 'smoke zone' such as to conduce to high agricultural development? (2) Does there exist in the 'smoke zone' any soil trouble which is responsible for any poor condition of plant growth which may exist? (3) Has the soil of the 'smoke zone' been polluted by materials deposited therein from smelter smoke? (4) If such pollution exists, is it of economic importance? May it influence the growth of crops or plants for good or for ill?

The yield of crops in the area is below the average for areas in other parts of the state having the same climate. The poor quality of the soil and the poor agricultural practices are sufficient to account for the existing bad conditions as to crops and crop yields. No soil trouble exists, other than the poor quality of the soil, to which the existing conditions of plant growth can be traced.

In the matter of soil pollution, an extensive investigation was conducted. Samples of soil were taken from various portions of the area and subjected to examination to determine the presence of lead and arsenic. These metals were found to be natural constituents of the soils of the 'smoke zone' and the country surrounding it. A slight increase in the lead and arsenic present in the soil was found in the area nearest the smelter, but this increase was shown to be of no economic importance. Supplementing this work, the data collected by Mr. Wells on the presence of lead and arsenic in the air before the building of the roaster bag-house proved that although there was lead and arsenic present, the amount was unimportant from the point of view of soil contamination.

Damage to Animals

The veterinary survey included the identification of every horse and the enumeration of all the other important domestic animals within the zone. The listing of the horses developed the fact that 31 horses out of a total of 308 within the 'smoke zone' were suspected as being of the type known as 'roarers.' Twelve of these 31 were diagnosed as 'roarers,' the 'roaring' condition being brought about directly by the paralysis, either part or complete, of certain muscles of the throat and neck, which causes improper functioning of the respiratory system, so that under exercise the animal so affected breathes with a peculiar roaring sound. In the opinion of the experts, the condition of these roarers was due to chronic lead poisoning and that the animals had been injured by smelter smoke.

Soon after beginning its investigations, the commission came to the conclusion that a study of the atmosphere of the 'smoke zone' uncontaminated by the visible element of the smoke of the Selby smelter would be highly desirable. The Selby Smelting & Lead Co. was, thereupon, requested by the commission to take steps to remove all solids from the smoke that was being discharged from the plant. The Selby company, with commendable promptness, began the erection of a bag-house, by means of which the visible smoke from the roaster stack (the only source of visible smoke) could be eliminated. The commission's request was made October 25, 1913, and the installation of the bag-house was completed April 1, 1914, at an expense to the Selby Smelting & Lead Co. of approximately $35,000.

Studies of the Sintering Machines.

In order that full information might be at hand upon which to base recommendations for the subsequent operation of the smelter, in the event that a nuisance was found to exist within the 'smoke zone,' the commission early undertook certain studies to determine the possibility of eliminating the sulphur dioxide from the smoke of the plant before the latter is sent into the atmosphere.

An investigation was conducted to determine the possibility of operating the Dwight & Lloyd sintering machines of the plant in such a manner as would allow the production of a gas with a sulphur dioxide content sufficiently high for its recovery as a by-product. As a result of this investigation, it was found that by a proper preparation of the charge and the re-circulation of a part of the gases, that 80% of the total sulphur dioxide eliminated by the machines can be concentrated in a volume containing 7.5% sulphur dioxide. With this concentration it is possible to apply a commercial scheme for recovery by the production of sulphuric acid, liquid sulphur dioxide, or sulphur.

Findings of the Commission

From the personal investigations by the commission and from a study of the various reports presented, the commission finds that the Selby company violated the injunction up to April 1914, with respect to damage to certain horses in the 'smoke zone,' and that this violation ceased when the roaster stack bag-house was erected; Selby company has not violated the injunction with respect to disagreeable odor maintained in the 'smoke zone,' nor with respect to injury produced on crops or vegetation or on domestic animals through emitting sulphur dioxide into the atmosphere; the Selby company will not violate the injunction if it discharges less than 80 tons of sulphur dioxide per 24 hours into the atmosphere, and cleans the smoke of its visible element; the Selby company will not violate the injunction, if for purpose of cleaning or repairing the bag-house, visible smoke is discharged for periods not to exceed a total of 48 hours in any one month.

The Victorian state coal mine, Australia, produced 510,490 tons of coal during the past financial year. Sales amounted to 495,155 tons, as follows:

	Screened.	Run-of-mine.	Slack.	Total.
Government railways..	297,381	8,941	9,836	316,159
Other departments.....	10,957	1	1,815	12,774
General public	.....	....	166,221	166,221
Total	308,338	8,942	177,872	495,154

The selling price of coal per ton, delivered into cars at the pit mouth, at June 30, was:

	Screened.	Run-of-mine.	Slack.
To railway department	$2.64	$2.04	$1.56
To other public departments	2.76	2.04	1.68

There were 1011 men employed, and 457 miners averaged $3.36 per day. After every expense was paid, including depreciation and sinking fund, the profit was $5800.

Diamond mining in South Africa is at a low ebb on account of the war. In July there were 5018 Europeans and 40,861 natives employed at producing mines, compared with 233 and 101, respectively, in September. Non-producing properties, where no underground work is being done at present, are employing 2807 white men and 1776 colored men.

Butters' Salvador mine, Central America, yielded a profit of $29,000 from 3200 tons of ore in October. The mill recovery was 87.5 per cent.

SMELTING FURNACE AT SEMINOLE MINE.

Gold Mining in Georgia

By CLAUD. HAFER

The illustration shown above is that of what may be called a 'toy' smelter. It is at the Seminole copper-gold mine, 45 miles from Augusta, Georgia. This furnace was built ten years ago, and operated intermittently to smelt second-class concentrate from the mine, which was too low in copper content to ship to smelting works. It is a 24 by 36-in. rectangular brick stack with water jackets on the sides and back, and with three 2-in. tuyeres at the back. Its capacity varied from 10 to 15 tons per day of ore and concentrate, and two carloads of matte and one ton of rich base bullion were produced. Approximately five tons of concentrate was run into one ton of matte. The concentrate was a mixture of iron and copper sulphides, with 20% of silica and a little galena. The material was briquetted by hand, using a mixture of cement and lime for the binder, and was smelted without any additional flux. A matte was made containing 15 to 20% copper, 20 oz. silver, and 2 to 3 oz. gold per ton. The difficulties of operating small furnaces are well known, but this furnace in the hands of the skilled metallurgist who built and operated it, worked remarkably well.

The mine is 12 miles from any railroad and the difficulty of securing transportation and the expense of wagon haul were factors in bringing to an end the operations that were carried on in a small way here for a number of years. As there is now a prospect of the early building of a railway to within easy reach, there is a strong probability that work will be resumed. This property is well known as being one of the most interesting of Southern gold-copper deposits and is described in *Bull.* 455 of the U. S. Geological Survey.

Five different orebodies or veins occur in a mineralized shear zone in mica schist, which is some 300 ft. wide, and has been intruded by basic dikes, and subjected to considerable faulting. The veins were worked by open-cut methods in ante-bellum days for their gold content, and were discovered through the means of placer work along Soap creek, which cuts across the mineral belt. At water-level the ores became refractory to the simple early day metallurgical methods, and work was abandoned to be resumed after the war, when the sulphide ores were exploited. These contain copper and lead as well as gold and silver. A shaft explores the

CONSOLIDATED CHLORINATION PLANT, DAHLONEGA DISTRICT.

formation to a depth of 225 ft., and at the 145-ft. level a long cross-cut exposes the mineralized schists and the different orebodies. The orebodies are as much as 15 ft. in width, and consist of quartz and silicious schist impregnated with chalcopyrite and galena. Adjoining the ore the wall rock is heavy with auriferous iron pyrite, which is, however, not sufficiently rich to be mined and treated under present working conditions. Some of the ore is rich enough to be shipped direct to smelting works.

The mill for this purpose is equipped with a Gates gyratory crusher, Colorado Iron Works rolls, Twentieth Century jig, and two Bartlett tables, with the accessory belt elevators, revolving screen, and classifiers. Its capacity is from 30 to 50 tons per 24 hours. The mill was not altogether satisfactory, and in the event of commencing work again, stamps and Wilfley tables will be used as well as copper plates for amalgamation, as there is free gold in the semi-oxidized ore, and the big waste dump that has accumulated during many years, contains free gold in quantity to warrant re-milling.

The second photograph is that of the Consolidated Chlorination Works in the Dahlonega mining district. This was built in the boom days, early in the past decade, and has long been inactive. The plant's original capacity was 30 tons of sulphides daily, and the tonnage was to have been supplied by the 120-stamp combination amalgamation and concentration mill nearby. Plants of such size were out of place in Dahlonega and the result has been the nearly complete paralysis for years of this old mining district.

The Dahlonega district is today a museum of mining and in its limits one can find equipment of all kinds: dredges, pipe-lines, mining ditches, an abandoned electric tram line, and heavy pumping plants for supplying water for placer operations. There are some 500 stamps, ranging in type from modern heavy heads mounted on concrete blocks, down to primitive mills employing wooden mortars, made of a single hollowed out log lined with iron, and wooden stamps with iron shoes. The Southern miner is not less persistent than his brother of the West and effort is still being made to continue the work that was commenced here near a century ago. One company, whose personnel includes individuals who were victims of the boom, is putting up a small plant that is a modification of the old Dahlonega method of hydraulicking and milling. The soft low-grade ore will be excavated by means of a hydraulic giant working under a pressure of 90 ft. A 1500-ft. flume fitted with riffles to catch any nugget gold will transport the broken material to the mill where a revolving screen will be used for sizing. The coarse rock, after sorting, if feasible, will be milled in a 10-stamp battery, and passed over amalgamated copper plates. The fine material will be ground in a tube-mill without the addition of quicksilver, and passed over plates. If the tailing from either department is of sufficient value to merit secondary treatment, concentration, or cyanide equipment will be added. This installation is largely experimental, but on a sufficiently large scale to be profitable, if it proves to be technically successful when placed in operation.

The concensus of opinion among those who should know, is that the mines of Dahlonega under proper management can furnish plenty of low-grade quartz ore, so its future rejuvenation is possible. In recent years a large pyrite deposit was discovered near Dahlonega. Its outcrop has been traced 2000 ft., and on the dip it has been explored 150 ft. Its thickness proved by cross-cuts, trenches, and drill holes, is from 20 to 30 ft. An average sample of 8 cars taken across the vein gave the following result: S, 43.52%; Fe, 39.70%; Cu, 3.09%. As the deposit is a bedded vein of the Dahlonega type, it undoubtedly contains small amounts of the precious metals, and it is not likely that the average copper content is as high as the assay indicates. At all events this ore is a valuable source of sulphur dioxide for making sulphuric acid, and the residue may be leached to recover the copper, after which the iron oxide can be nodulized and sold to furnaces, as is being practised by the North Carolina Ore corporation at Winston-Salem, North Carolina.

Smelting the residue with the silicious gold ores from other mines, to an auriferous copper-iron matte, would be of the greatest benefit to the district, but all of this depends on cheap transportation to carry out the different products, and to bring in fuel and other supplies (charcoal locally made might be used as fuel), and at present there is no railroad nearer than 15 miles.

A Bottomless Scraper

In various Alaska placer districts a bottomless scraper bucket, known as the Bagley, is used with good results. It is illustrated in the accompanying figure. The bucket is hitched with a bridle as shown and is managed by

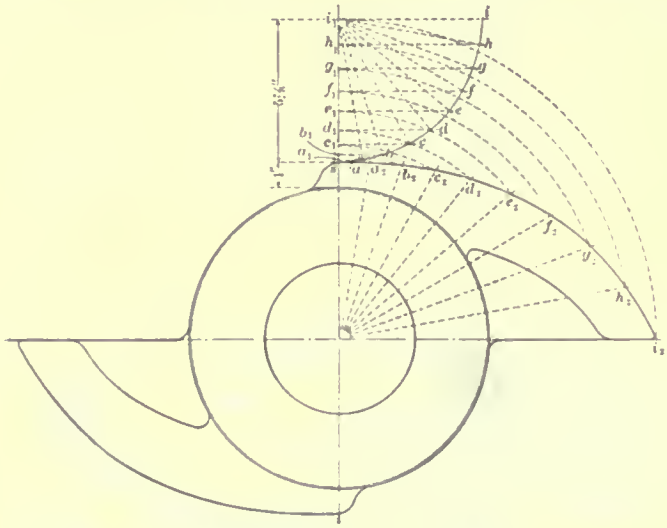
means of tail rope and lead rope. It fills and then rises and rides over the material below. There being no bottom, wear is less and at the same time the presence of a top and arrangement of the ropes assures a full load. This bucket is especially useful in heaping up soft material. The one pictured is in use on Otter creek in the Iditarod district to transport gravel from a winter dump to sluice boxes.

Improved Cam for Stamp-Mills

By ARTHUR B. FOOTE

*The cams at present universally used in stamp-mills lift the tappets with an involute form of curve, to which the surface of the tappet is always tangent; moreover, the line of contact between tappet and cam, if produced, would pass through the centre of the stem. This is no doubt a desirable feature, but the writer has long believed that it would be much more desirable if the cam were to pick up the stamp without shock and gradually increase the upward velocity of the stamp throughout its upward movement. The involute form of cam attempts to impart instantly a considerable upward velocity to the stamp, starting it from a state of rest, and the result is a destructive blow, a great deal of noise, and much wear and vibration.

The writer has developed a form of cam which will lift the stamp with a motion similar to that of the



METHOD OF LAYING OFF CAM.

piston of an engine between the end and middle of its stroke; in other words, harmonic motion, from the point of zero to maximum velocity. The curve will give this ideal motion only when the stamp is set for the exact drop for which it was designed, but the improved cam will not be as bad as the involute cam until the drop is reduced one-half. In other words, if a cam is designed for a 6-in. drop, it will be some improvement over the usual form of cam until the drop is only 3 inches.

Any cam, whatever its form, must of course lift the stamp in the same number of degrees of revolution; therefore, with this new form, since the stamp starts more slowly on its upward course, it must end by going faster, the average speed being the same as with the involute cam. The stamp, after it is no longer in contact with the cam, keeps on going up a certain distance, which is easily calculated. It is, therefore, possible to hang up a stamp without a cam-stick, if the fingers are not more than $\frac{1}{8}$ in. longer than necessary to hold the tappet above the cam.

With this design of cam the surface of the tappet is not tangent to the surface of the cam throughout the lift. The possible consequences of this were studied with a full-size model, and did not seem serious, as the engagement between the surfaces was an easy sliding motion, instead of a blow. If the drop is shortened, the blow becomes more and more pronounced, but the surfaces also become more and more nearly tangent.

Five cams of this new design have been running in one of the mills of the North Star Mines Co. now for over a month, fulfilling every expectation of the writer. Holding the hand on the tappet, it is impossible to feel the cam strike the tappet, although the stamps are dropping 107 times per minute.

The cut shows the method of laying off the curve of the cam, which will give approximately harmonic motion to the stamp. Spaces $s\ a_1$, $a_1\ b_1$, $b_1\ c_1$, etc., represent the distances traversed by the stem in equal intervals of time.

Charles W. Taylor, president of the Taylor Foundry & Engineering Co., of Grass Valley, California, rendered valuable assistance with this new cam.

*Paper presented to Am. Inst. Min. Eng., New York meeting, February 1915.

GOLD AND SILVER PRODUCTION of Honduras in August and September was as follows in ounces:

	Aug. 1914.	Sept. 1914.	Aug. 1913.	Sept. 1913.
Gold	1,260	1,291	878	1,114
Silver	167,995	161,424	121,170	163,968

According to a *Consular Report*, the European war has caused a material increase in the operating expenses of the mines. Cyanide has increased in cost 50%, zinc dust 100%, and tube-mill supplies 35%, all of which represents an added cost of approximately 70%. Zinc dust, classed as an explosive by United States transportation laws, can be shipped only on freight vessels, and boats carrying only freight do not touch at the Honduras Pacific port. *Revista Economica*, of Tegucigalpa, Honduras, has been publishing a series of articles dealing with the mineral resources of the Central American republics, including Honduras. The republic owes its prosperity under Spanish rule, and the greater part of its present progress, to its mineral resources.

GOLD YIELD of eight properties in West Africa in October amounted to 38,879 oz. The total for 1913 will be about 25,000 oz. more than in 1913, when it was 397,679 oz., against 362,940 oz. in 1912. Individual returns were as follows:

Mine.	Ore treated. Tons.	Gold recovered. Value.
Abbontiakoon	12,015	£19,065
Abosso	9,351	19,596
Akoko	233	980
Ashanti Gold Fields	10,064	37,225
Broomassie	4,543	16,652
Cinnamon Bippo	2,628	5,300
Prestea Block A	25,900	40,217
Taquah	5,670	16,826

Persistence of Ore at Kolar

By T. A. RICKARD

*In the Kolar goldfield of India the prevailing country rock is the Dharwar schist, which is hornblendic and pre-Cambrian.[1] This is traversed by lodes that in their strike (8° west of north) and in their dip (40 to 70° west) conform to the foliation of the schist, so that these ore deposits may be regarded as veins formed along planes of fracture coinciding with the foliation.[2] The coincidence is not perfect everywhere, for, as might be expected, the later fractures in places found an easier way by diverging slightly from the earlier structural lines of weakness.[3]

All the noteworthy mines are on one lode—the Champion Reef—but several subordinate veins have been exploited profitably. The orebodies represent the richly gold-bearing portions of the quartz veins; even where a vein becomes too poor to be mined the quartz may persist. From Plummer's shaft in the Mysore mine to Kennedy's shaft in the Nundydroog, a distance of three miles, the main lode is continuous except where intersected by dikes and cross-courses. At some levels this lode has been persistently profitable for 7000 ft. on the strike. The folds in the country rock do not interrupt this continuity; on the contrary, the orebodies are most generous in width where the schist has undergone a sharp fold, making a pleat, the axis of which marks the pitch of the shoot. The longitudinal sections of the four principal mines indicate that the various orebodies are comparatively uniform in their pitch, at an angle of 45° north. This fact has had an important bearing on the history of individual mines, for it has caused sundry ore-shoots to pass from one property into another. The width of ore averages about 4 ft., but stopes as wide as 35 ft. are recorded.

Of the seven properties linked along the main lode, four have become great mines; the other three need not be discussed in connection with the persistence of ore in depth. The length of the four productive properties

[2]F. H. Hatch, 'The Kolar Goldfield,' *Memoirs* of the Geological Survey of India, Vol. XXXIII, Part 1 (1901).

[3]For this note I am indebted to Arthur Llewellyn, formerly in charge of the Survey and Geological Department of the Kolar group of mines.

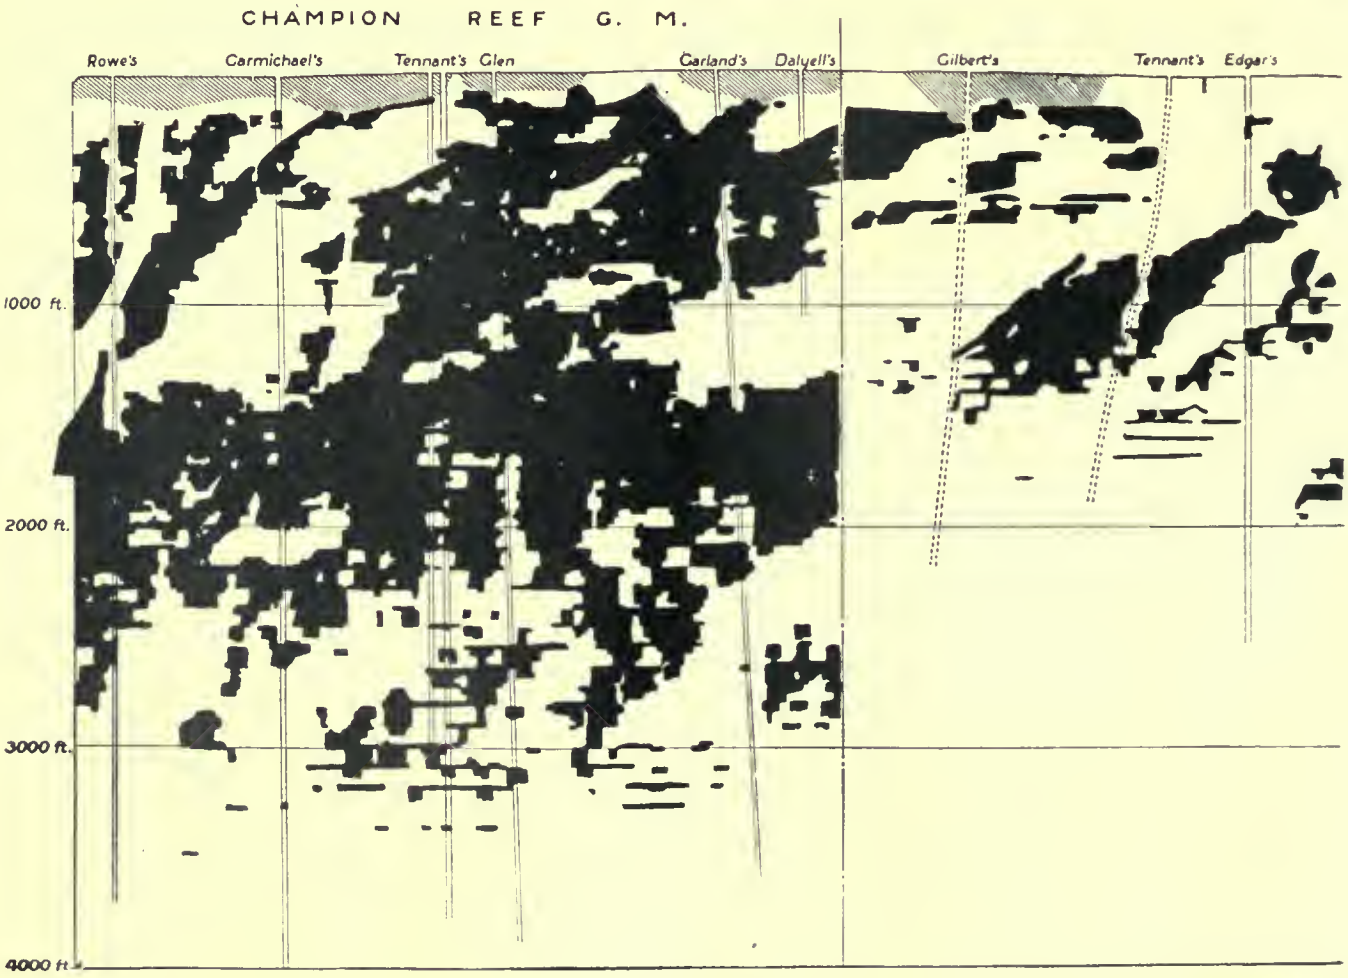

FIG. 1. LONGITUDINAL SECTION OF MYSORE OREBODY;

and the depth of their workings are given herewith, in feet:

	Extent of property on lode.	Depth on the dip.	Vertical depth.
Mysore	7847	5000	3465
Champion Reef	3506	4700	4340
Ooregum	3355	5100	4670
Nundydroog	6198	3200	2756

For many years the yield from these deep mines was so steady that the Kolar goldfield became a stock example of persistence, if not enrichment, in depth. This hasty inference was as fallacious as the suggestion, made in 1904, that a flattening of the lode presaged a speedy end to a highly productive industry.[4] Leaving geological inferences of doubtful value, I find that the statistical record indicates impoverishment in depth, but sagacious management has decreased the cost of exploitation to such an extent that the economic result has continued to be most satisfactory.

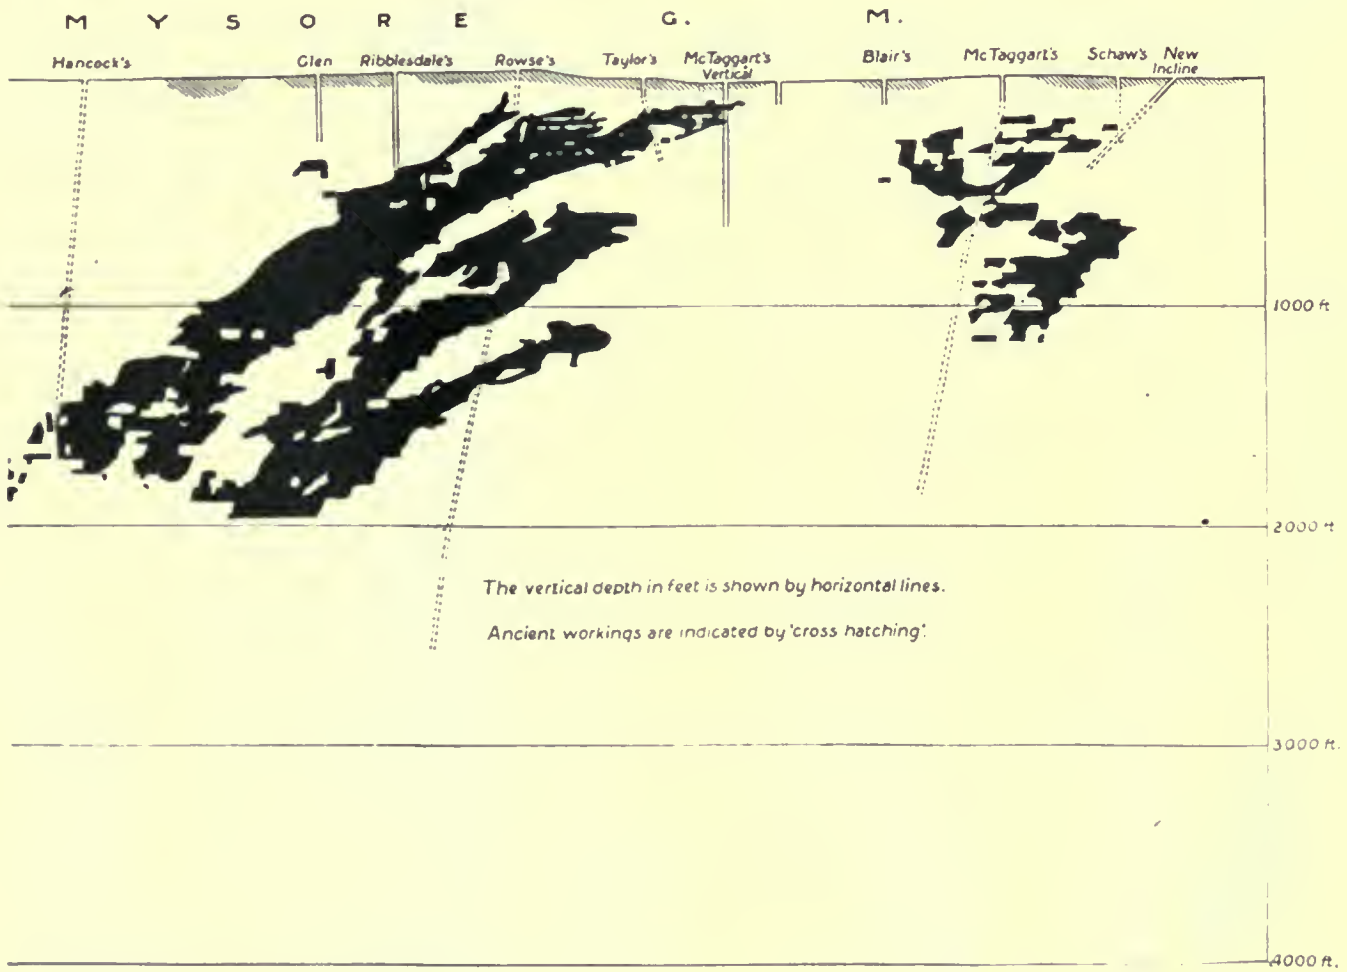
Of the four principal mines, the most northerly, the Nundydroog, has two ore-shoots, 1800 ft. apart. The lower levels became decidedly poor in 1908 at a depth of 1200 ft. Subsequently the mine gave good results, and the output of ore was gradually increased. Eighteen months ago, however, the bottom workings appear to have passed through the principal ore-shoot at 2500 ft., the output becoming curtailed pending further developments.

On the Ooregum, which comes next southward, the ancients followed the richest spots down to 250 ft.,[5] and dug into the vein along the entire length of outcrop within the limits of the property. The first orebody exploited was traced from these old workings to 750 ft. in depth, where it diminished in length and richness; but an ore-shoot pitching north from the Champion Reef crossed the southern boundary, and enriched the lode from 1260 to 2000 ft. Under this came a third shoot, which was broken by a dike near the south boundary, but made again 1000 ft. north on the 3000-ft. level, from which it has been traced to the bottom of the mine at 5100 ft. on the dip.

In the Champion Reef the old workings reached to 275 ft. This mine did handsomely until about six years ago, when it was 3700 ft. deep. Since then the length of stoping ground has contracted. An examination of the qualitative stope-section shows that impoverishment began at the south end and on the 9th level. Down to the 16th the mine was 'sick.' Then the upper Tennant's shoot from the Mysore crossed the boundary, and for five levels ore was almost continuous from boundary to boundary—3500 ft. Again for 12 levels the lode was

[4] 'Geology of the Kolar Goldfield,' by A. M. Smith, *Trans.* Inst. M. & M., Vol. XIII, pp. 152-180.

[5] Unless otherwise stated, all the mine measurements are taken on the dip of the lode.

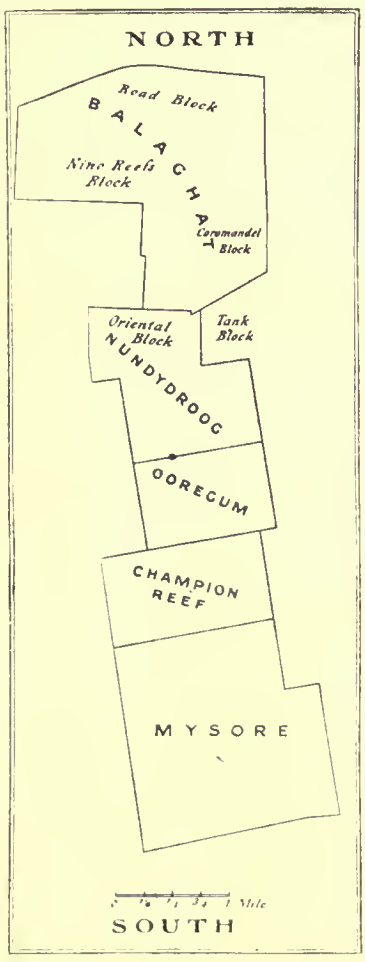


PARTS IN BLACK INDICATING THE ORE STOPED.

poor and patchy. Then an improvement became apparent, on the 33rd level, where, at the south end, the lower portion of Tennant's shoot crossed the south boundary and gave renewed encouragement.

The Mysore is the great mine of the Kolar district. It extends for 1½ miles along the lode, and includes ten distinct ore-shoots. In places three or four orebodies are found overlapping. The ancients worked to a depth of 300 ft. at the north end of the mine, where Gilbert's shaft was sunk, but this orebody proved disappointing. Below it, however, came Tennant's shoot, which did not outcrop, but ended at about 450 ft. from surface. Under Tennant's, and close to it, comes another. Indeed, in this mine the three principal runs of ore have the form in each case of twin ore-shoots. Crocker's shoot is the most regular and persistent in the goldfield; it has had a length of 1500 ft. of continuous high-grade ore. Impoverishment appeared at 1600 ft., followed in depth by alternations of yield, the latest stage being impoverishment for 700 ft. McTaggart's shoot, also in two divisions, one pitching under the other, reaches to within 200 ft. of the surface, but does not outcrop. It is enriched at 1660 ft., and for 1000 ft. in depth, becoming poor at 2800 feet.

In this gold-mining district the existence of ancient workings proved as much an obstacle as a guide in the first operations, because the unknown former workers had removed all the rich and easily accessible ore to a depth reaching nearly to 300 ft. under the surface.



The present industry owes its origin to an Irish soldier named Lavelle, who began prospecting in 1871 and obtained a concession two years later. In 1876 he transferred his rights to a syndicate—the Kolar Concessionnaires—formed by the late General de la Poer Beresford. The first working capital was furnished by Arbuthnot & Co., of Madras, but this famous mercantile house retired from the venture at an early stage. In 1880 the firm of John Taylor & Sons was invited to assist the enterprise. This was done after the late Bell Davies had reported favorably. But for three years the results were most disappointing, and it was due to the pertinacity of the engineers, more particularly John Taylor, that the work was pushed to eventual success, aided by the financial support of the late Sir Charles Tennant. How complete that success has been is proved eloquently by the statistical record:

	Ore, short tons.	Gold, fine oz.	Dividends.
Mysore	3,917,109	3,603,112	£7,414,344
Champion Reef	3,179,185	2,502,292	4,018,966
Nundydroog	1,526,554	1,241,808	2,002,768
Ooregum	2,402,346	1,562,829	2,214,320

In his earlier paper, F. H. Hatch gives the yield of gold per ton in 1899; this can be compared with that in 1913, by converting the standard gold as recorded in the annual reports into the fine gold quoted in the geological memoir. Another correction must be made for the use of the short ton (2000 lb. avoirdupois) in some of the later reports as compared with the long ton (2240 lb.) of the earlier statistics. Making these corrections, I find that the yield of the four big mines compares as follows in pennyweights of fine gold per short ton:

	1899.	1913.
Mysore	27.68	14.29
Champion Reef	26.41	10.92
Nundydroog	19.60	15.95
Ooregum	14.04	13.92

The decrease in yield is apparent: whether it is due to the treatment of a larger tonnage or whether, conversely, the necessity for treating a larger tonnage arises from the lower grade of the ore, is not obvious. Other evidence suggests that there is a real impoverishment, which has been largely compensated by a cheapening of the processes of exploitation. This is indicated by a comparison of the cost incurred at the two periods, in shillings per short ton, as follows:

	1899.	1913.
Mysore	33.36	24.24
Champion Reef	42.34	26.55
Nundydroog	39.28	30.33
Ooregum	40.53	22.68

These figures do not give the total cost. Among the items omitted are: (1) the royalty paid to the Mysore government, at the rate of 5% of the gross value of the gold, *plus* 2½% on dividends distributed since March 1910[6]; (2) the English income tax; and (3) the depreciation of, or expenditure on, shaft-sinking, plant, and machinery, this item being differently treated at the two periods under comparison. The actual total cost is about 50% more than the 'working' cost or revenue expenditure. However, that does not affect the comparison, for it applied as much in 1899 as in 1913. On the other hand, while the cost has not decreased as much as the yield, the dividends have increased considerably in some cases, as the following comparison indicates:

	1899.	1913.
Mysore	£350,000	£381,250
Champion Reef	275,000	130,000
Nundydroog	72,600	99,050
Ooregum	65,000	129,250

[6]The extra impost has been paid to the government since the renewal of the leases.

This favorable result is due mainly to the increased tonnage:

	1899.	1913.
Mysore	103,424	302,662
Champion Reef	104,296	220,511
Nundydroog	39,424	90,650
Ooregum	71,800	153,636

Obviously these statistics do not bear directly on the geological problem before us, simply because mineral exploration is not conducted with a view to elucidating scientific questions.

In Fig. 1 are shown the portions of lode area that have actually been stoped. This does not show all the ground that is ore bearing, of course; but it serves to indicate the shape, size, and trend of the orebodies.

Structure Controlling Ore-Shoots

The question of continuity of ore in depth is also complicated by the flat pitch of the successive ore-shoots. This feature need not, of course, perplex any intelligent observer now, but in the early days of the mines, before the geological distribution of the ore had been ascertained, it was, undoubtedly, a hindrance to confident exploration. The Mysore, for instance, passed through several periods of depression. In the Company's office a transfer of 200 shares at 9d. is still preserved as a memento of the dark days of 1883. The ore under the old workings near Gilbert's shaft appeared to 'peter out,' although it really sloped flatly across the adjoining boundary into the Champion Reef property. A long exploratory level at 1100 ft. had been extended for 3000 ft. without finding anything of particular promise, for the rich part of Tennant's shoot was underfoot and Crocker's orebody was farther south. Such eras of depression have been repeated not only in the history of the Mysore mine, but in that of the Kolar goldfield as a whole. It is the barest justice to state that the persistence of intelligent effort on the part of the management cannot be discounted even by one who finds it necessary to question the persistence of the ore. Two outstanding facts in the history of this group of mines are: (1) the uninterrupted technical control of operations by the oldest mining firm in London, and (2) the complete detachment of those operations from share-gambling. The lode has been exploited for the gold to be extracted, not as a counter in Stock Exchange manipulation. To these two facts is owing, largely, the ability of the mining companies to obtain financial support, whenever necessary, from a large body of absolutely loyal shareholders. The history of Kolar constitutes one of the best pages of the mining record.

Returning to more technical considerations: A careful examination of the longitudinal sections of the four principal mines will show how the successive ore-shoots slope one under the other, often in pairs, at an angle of 45° with the horizon, tending, however, to spread apart in depth northward. This spreading is due to a flattening of the fold, the structure of which was a determining factor in the deposition of the ore. The shoots are not always continuous bodies of ore, but represent favorable structural conditions, having a fairly regular pitch, which, as I have said, coincides with the axes of the folds in the schist. The decreasing pitch of the ore-shoots and the apparent spreading or fanning of their axial lines points to a diminution in the acuteness of folding or intensity of plication. This is an unfavorable change in the geological structure.

This structure explains many of the vicissitudes recorded in local history. Vertically the distance between ore-shoots is considerably greater than the interval separating them at right angles to their pitch. When an ore-shoot, like that at Gilbert's shaft, was lost in depth, it was not until long afterward that the stope-section showed that it had passed flatly across the boundary into the adjoining mine. At least two ore-shoots in the Mysore did not outcrop, and therefore were not easily found. The general effect was to accentuate unduly the alternations of depression and prosperity, and to exaggerate the intervals of poverty and richness. On the other hand, as the mines have become healthily enlarged, the managers have provided against fluctuation of output by allowing large reserves of ore to accumulate, whereby to help the lean years and obviate anxiety to their shareholders. Thus, at the present time, the Mysore has 1,377,000 tons of ore in reserve, this being equal to over four years' supply. As regards the immediate subject of this paper, the output for successive years does not correspond with increasing depth because the ore milled in 1914 may come from stopes two thousand feet higher than the bottom level; in other words, the depth of the mine in any year bears no direct relation to the quality of the output. Of this, of course, the economic geologist must be aware, lest he fall into inferences of a most misleading character.

Gold output of Rhodesia in October was £337,241, against £309,398 in September. Ten months of this year show an increase of more than £50,000 over that for the whole of 1913. There were 219 producers during the month. Some individual returns were as under:

Mine.	Ore treated. Tons.	Gold recovered. Value.
Antelope	3,377	£ 7,551
Bell Reef	3,200	7,491
Cam & Motor	12,435	17,109
Eldorado	5,228	11,123
Gaika	3,000	7,476
Giant	6,000	112*
Globe & Phoenix	....	27,000*
Lonely Reef	4,030	11,127
Rezende	10,500	3,786
Shamva	48,489	41,348
Thistle-Etna	2,132	3,359
Transvaal and Rhodesia Estates	2,050	6,100
Wanderer	12,160	1,903*

*Profit.

Gold output of the Indian mines in October was 50,818 oz. This year's total will be about 8000 oz. more than in 1913. Eight mines are producing.

Concentrate Treatment Costs at the Treadwell Cyanide Plant

By W. P. LASS

The Treadwell cyanide plant treats concentrate recovered by Frue vanners from ore crushed by 900 stamps in the mills of the Alaska Mexican, Treadwell, and United companies on Douglas island, near Juneau. The following table, made up from the records, shows detailed costs at the plant during June 1914, when 3023.30 tons of material was treated:

COSTS PER TON

	Grinding.	Dissolving.	Filtering.	Precipitation.	Refining.	Total.
Direct labor:						
Operating	$0.140	$0.245	$0.163	$0.085	$0.213	$0.846

Total	$2.513	$2.766	$2.941	$3.293

Supplies consumed are as follows:

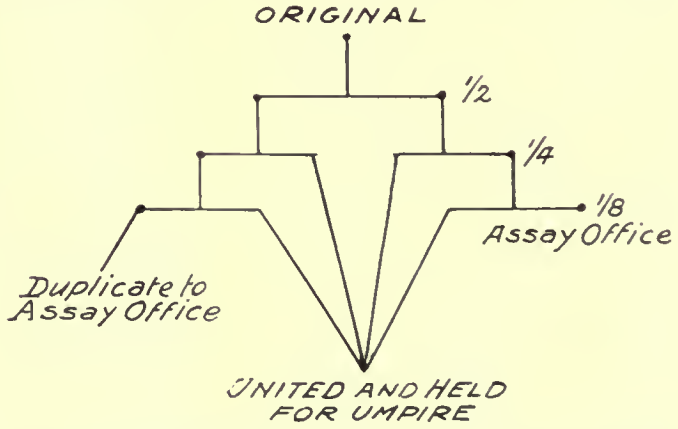
Material.	Amount, pounds.	Cost per ton.
Cyanide	2.38	$0.549
Lime	6.74	0.058
Pebbles	7.28	0.050
Zinc dust	2.00	0.141
Precipitating paper	....	0.011
Precipitating cloth	....	0.003
Filter-cloths	....	0.009
Electric power, kilowatt-hours	28.72	0.070

During June the concentrate averaged $52.6074 per ton before, and $1.8177 after treatment, showing an extraction of 96.5 per cent.

The cyanide plant began treating the Douglas Island concentrates in September 1910, and for the first three months the estimated extraction was 97%, while the actual gold extraction as represented by the assay value of the heads and the actual bullion shipped plus the plant's gold inventory was but 90%. Since then the actual extraction has at all times exceeded the estimated extraction.

The estimated extraction is based on the assay value of the head and the assay value of the dry sands plus the value of the sluicing-out solution.

The assay value of the heads is determined from the daily samples as taken by a ship's auger from each of the cars. This sample, after drying and moisture determination, undergoes two cut-outs. Assays are made from the extremes of the quartering as shown by the diagram below:



Thus all samples have duplicate cut-outs, to which separate numbers are given for assay purposes, though

they may not be sent in for assay on the same day. In this manner an individual eheck is obtained upon each assay and the value ealculated upon the average of the two. In case the two assays vary by more than 5%. two new cut-outs are made from the original sample and the accepted value ealculated from the three nearest values. At the end of the month the assayer is acquainted with the accuracy of his results.

The work is checked by making a composite sample from each of the daily rejects or umpire samples by taking an amount in ounces from each sample equal to the tons in the lot from which the day's sample was taken. Thus the monthly eomposite sample eontains the same number of ounees as tons of the original ore from which sample was taken. This composite sample is eut down and assayed in the same manner as the daily samples were assayed. If the value of this sample does not eheck with the value as ealculated from the daily assays. all the work may be checked over until the erratic assays are eliminated.

The following cost-sheet shows the detail cost per assay for the year 1913. This sheet is based upon an inventory of the stock on hand at the end of each month. and aids the assayer in keeping stoek.

ASSAY OFFICE REPORT, YEAR ENDED DECEMBER 31, 1913

Item.	Used during year. Quantity.	Amt.	Cost per assay.

METAL PRODUCTION of Queensland has been considerably affected by the war. The output for the September quarter is as follows:

Product.	Sept. quarter 1913 (tons).	Sept. quarter 1914 (tons).
Copper	6,033	3,410
Silver (ounces)	156,954	30,709
Tin	952	362
Lead	923	105
Wolfram	93	34
Bismuth	0.5	0.2
Molybdenite	11.5	1.75
Manganese	25	.....
Ironstone flux	1,061	8,359
Limestone flux	41,979	27,046
Bismuth-wolfram	45.75	0.75
Total value	$2,785,000	$1,200,000

Production for the nine months ended September was $2,260,000 less than for the corresponding period of 1913. The gold yield in October was 22,713 oz. fine, an increase of 3078 oz., and 199,342 oz., or 20,711 oz. less than the same period of 10 months of last year. Molybdenite is $22.80 per unit.

ORE RESERVES in the New Modderfontein mine, on the Rand, total 6,300,000 tons averaging 8.40 per ton. Operating costs total $3.58 per ton.

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

Valuation of Dredging Ground

The Editor:

Sir—The various methods of calculating the average value of dredging ground, as shown by the letters in recent issues of the *Press* are interesting because they illustrate that mistakes can readily be made in a comparatively simple matter, and although Mr. Herzig has forestalled me by sending the correct solution, I am submitting mine, which is, I am sure, based on first principles.

In the accompanying sketch, Fig. 1, it is required to

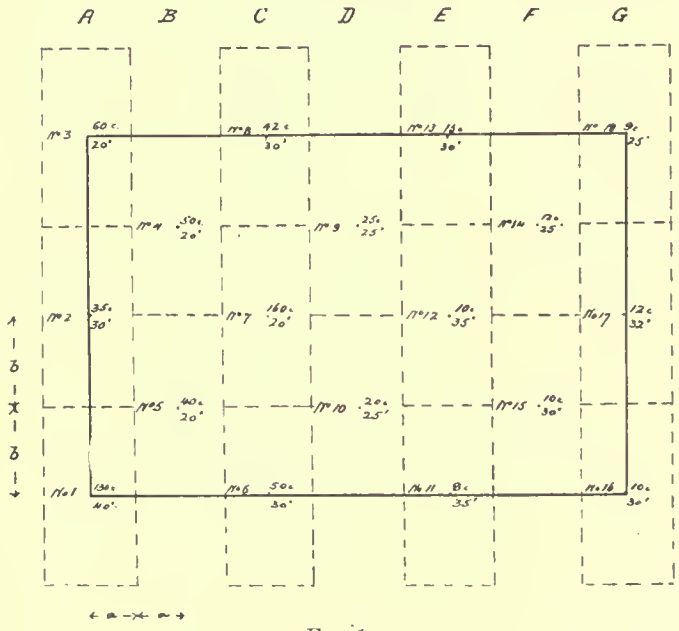

Fig. 1.

find the average value and depth of the portion within the full lines, and the dotted lines represent the ground prospected, a value and a depth being shown in the centre of each dotted rectangle. Incidentally it may be mentioned that Mr. Decoto's average (37.69c.), published in your issue of May 9, is correct for the ground enclosed in the dotted lines.

The average value is the total value divided by the cubical contents of the ground in question, and in order to arrive at the latter, let us assume that the distance between the lines of holes is $2a$ and that between the holes is $2b$. By this assumption, fractions will be avoided.

Referring now to hole No. 1, we see that the area to be included in our calculation is $a \times b$, the volume is $40ab$ and the value contained therein is $5200ab$.

By similar calculations the following results may be obtained:

1.	$a \times b \times 40 \times 130$	$= 5{,}200ab$
2.	$a \times 2b \times 30 \times 35$	$= 2{,}100ab$
3.	$a \times b \times 20 \times 60$	$= 1{,}200ab$
4.	$2a \times 2b \times 20 \times 50$	$= 4{,}000ab$
5.	$2a \times 2b \times 20 \times 40$	$= 3{,}200ab$
6.	$2a \times b \times 30 \times 50$	$= 3{,}000ab$
7.	$2a \times 2b \times 20 \times 160$	$= 12{,}800ab$
8.	$2a \times b \times 30 \times 42$	$= 2{,}520ab$
9.	$2a \times 2b \times 25 \times 25$	$= 2{,}500ab$
10.	$2a \times 2b \times 25 \times 20$	$= 2{,}000ab$
11.	$2a \times b \times 35 \times 8$	$= 560ab$
12.	$2a \times 2b \times 35 \times 10$	$= 1{,}400ab$
13.	$2a \times b \times 30 \times 15$	$= 900ab$
14.	$2a \times 2b \times 25 \times 12$	$= 1{,}200ab$
15.	$2a \times 2b \times 30 \times 10$	$= 1{,}200ab$
16.	$a \times b \times 30 \times 10$	$= 300ab$
17.	$a \times 2b \times 32 \times 12$	$= 768ab$
18.	$a \times b \times 25 \times 9$	$= 225ab$
	Total	$= 45{,}073ab$

Thus the gold content is represented by $45{,}073ab$ and dividing this by $48ab$, the area of the ground in question, gives 939.02 as the product of the average value and the average depth.

To find the average depth, let us represent line A graphically, thus, Fig. 2:

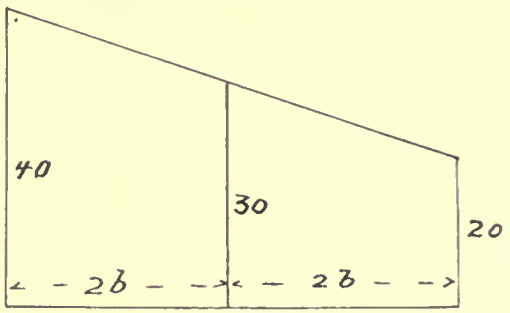

Fig. 2.

This shows the depths of the bore holes and the distances between them and the area of this figure is:

$$\frac{2b(40+30)}{2} + \frac{2b(30+20)}{2} = 120b$$

And since the base has a total length of $4b$, the average depth is $120b$ divided by $4b$ or 30. By similar calculations, the average depth of each line will be found to be: line A, 30; line B, 20; line C, 25; line D, 25; line E, 33.75; line F, 27.5; and line G, 29.75.

These results may be graphically represented as in Fig. 3 on the following page.

Since this line is at right angles to the previous ones

the distance between the lines, namely $2a$, is shown, and proceeding as before, we find the total area to be $(322.25)a$, which, divided by $12a$, gives 26.854 as the average depth.

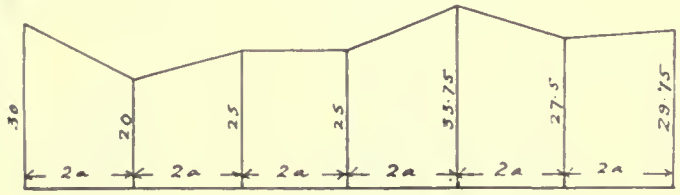

FIG. 3.

Previously we found that the product of the average depth and the average value was 939.02, and this divided by 26.854, the average depth, gives 34.96 as the average value.

No units are designated in this calculation, as they make no difference provided that the same units are maintained throughout. The method employed herein is applicable to all cases whether the lines or bore holes are spaced evenly or unevenly, and the rules used by Mr. Herzig may be easily deduced from it. For practice, let some of your correspondents calculate the averages by taking the lines of bore holes horizontally or diagonally instead of vertically as in this calculation. The results will be found to be the same.

JAMES T. DIXON.

London, October 27, 1914.

The Pan as a Regrinder

The Editor:

Sir—In view of occasional contributions in regard to the inefficiency of the grinding pan as a regrinder, the following notes may be of interest to millmen:

I am treating an accumulated dump of concentrate, some of which dates back to the eighties, using an old silver-grinding pan from a scrap heap as a regrinder. The foundry which made the pan recommended a pulp ratio of 1 to 3, and a speed of 75 r.p.m. to get the best results. Under these conditions, the best that I could get was one ton of concentrate in 72 hours, ground through 150 mesh. I have varied the pulp ratio and speed, and with 12% moisture and 30 r.p.m. I get a result of one ton in six hours. With the thin pulp and high speed, it would seem probable that the centrifugal force would tend to throw the pulp away from the die. This principle would apply to continuous as well as intermittent grinding.

WILLIAM S. MANN.

Cisco, Placer county, California, November 20.

[Our correspondent does not give the mesh of the concentrate before treatment or the diameter of the pan. Assuming that it was from a 20-mesh screen, and the pan is 5 ft. diameter, with shoes and dies in order, his pan should do better work than one ton in six hours. It is hard to imagine a pulp with 12% moisture, in fact, this would be simply damp sand. A berdan pan would grind more than this quantity, but the pulp should have a ratio of at least one of concentrate to one or two of water, perhaps a little more. With a speed up to 50 r.p.m. the output ought to be increased. Thin pulp and a high speed do not result in pan efficiency. If carefully operated, the feed to a pan may be continuous, as grinding in charges is a slow process, unless the material is very rich. Intelligently worked, the pan is an efficient regrinder.—EDITOR.]

Steam Stamps From a Gold Miner's Point of View

The Editor:

Sir—It is with pleasure I answer Mr. Hardinge's argument in support of the conical tube-mill; not that I wish to minimize the usefulness of his mill, but I do wish to emphasize what may be the future practice with cylindrical tube-mills of large diameter, and to show that the shape of particle most suitable for concentration is open to discussion.

We will assume that the conical mill wherever used in competition with a cylindrical tube-mill will show less oversize, but this is no indication of efficiency unless the cost of classifying and grinding with the cylindrical tube-mill is greater than grinding in the conical tube-mill alone. Until such tests are made with mills of the same major diameters and all other conditions of operating identical, so far as practical, the relative merits of the two classes of tube-mills must remain in doubt. For example, it is hardly fair to compare a belt-driven mill with one geared direct with the most approved gears, when the saving alone due to the difference in the method of transmitting power is more than that probable from the substitution of one machine for another. So far as I know, the tests at the Calumet & Hecla were not made with the cylindrical tube-mill and classifier in a closed circuit. If Mr. Hardinge can quote the figures showing the cylindrical tube-mill working this way, say with a Dorr classifier and the power applied in the same way as applied to his conical mill, his argument will be overpowering. It is altogether beside the argument that the Company has paid so many millions in dividends.

Mr. Hardinge's argument, that the flattened particles are more easily concentrated than the more granular product from the Chilean mill, ignores the fact that my statement was that both the Chilean mill and conical tube-mills tended to flatten the particles of copper which were floated off, and the proof of this contention is the poor extraction from either mill on the concentrators. I mentioned the fact that the Lovett machine, which rolls the copper into balls and spirals, produces a product from which 20% more copper can be extracted on the concentrators than from the conical tube-mill discharge. As Mr. Hardinge says, "economic efficiency * * * certainly must be considered as being superior to mere supposition based on theory."

ALGERNON DEL MAR.

Los Angeles, December 10.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

CARGO through the Panama canal from August 15 to November 15 totaled 1,079,521 tons, carried in 185 vessels.

NATIVES EMPLOYED in Rand gold mines at the end of October numbered 170,438, against 150,012 at the end of December 1913.

CRUDE OIL EXPORTS from Peru from January to September, inclusive, amounted to 96,000 metric tons, or about 672,000 barrels.

COAL MINERS at the Point Elizabeth government colliery, New Zealand, averaged $4.46 per day in 1913. The output was 124,804 tons.

ORE HOISTED by Rand mines during the first half of the current year averaged 2,269,365 tons per month, against 2,547,082 tons in the same months of the previous year.

FUEL OIL used by railroads in the United States in 1913 amounted to 33,004,815 bbl. There was 29,145 miles of line operated by this fuel, the oil-burning engines covering 118,672,162 miles. An average of 3.60 miles was made per barrel of oil consumed. The navy used over 21,000,000 gal. of fuel oil in the fiscal year ended June 30, 1913.

AN EARTH TREMOR at the Village Main Reef mine, Johannesburg, on November 12, resulted in the death of one native and probably two others, while shaft pillars about 150 ft. vertical below No. 6 level of No. 2 shaft were crushed, and No. 9 and 10 stations fell in. The sand-filled stopes saved workings from serious damage. Earthquakes on the Rand were described in the *Press* of July 25, 1914.

CURRENTS are set up during the filling of locks at Panama, having a tendency to move a vessel to one side. A mixture of fresh and salt water affects the vessel more. In filling a chamber there is considerable surface disturbance; but in emptying, the surface is placid, and there is scarcely any tendency to move a vessel, according to R. H. Whitehead, who has studied the phenomena of water pressures and currents in the locks.

AN AERIAL TRAMWAY, 37 miles long, is to be constructed between Valencia and Nirgua in Venezuela by an English concern. It will be in sections of 10 kilometres, making six in all. Each is to be driven by its own motive power, electricity for the first section near Valencia, and either oil, gas, or steam power for the others. The contract states that the line must be completed within two years of starting erection, and will run for 99 years under certain conditions.

IN REFINING PETROLEUM, sulphuric acid is used mainly to remove the resinous matters and certain hyrocarbons such as olefines. These constituents are separated out in the form of residual sludge, of little value. The acid process has certain disadvantages. The new Edeleanu process uses liquefied sulphur dioxide, which is a comparatively simple system, and besides doing away with the acid troubles, the compound may be readily recovered from the solution and used again with little loss.

CONSIDERABLE LOSS of life and damage to property has been occasioned by explosions of dust in grain mills in the United States. An investigation was made recently by the millers and the U. S. Bureau of Mines. During the inquiry it developed that the following causes have been assigned to many of the explosions in milling plants in this country and abroad: (1) use of open lights, or naked flames, such as lamps, torches, gas jets, lanterns, candles, matches, etc.; (2) property fires; (3) introduction of foreign material in grinding machines; (4) electric sparks from motors, fuses, switches, lighting systems; and (5) static electricity produced by friction of pulleys and belts, grinding machines, etc.

THE EFFICIENCY of the average steam plant of the United States is less than 5%; that is, there is only about 5% of the heat energy in the fuel fed to a boiler furnace delivered to the bus bars of an electric plant, according to R. H. Fernald in the *Journal* of the Cleveland Engineering Society. Assuming 13,500 heat units are in a pound of coal used, the relative heat losses in a steam plant, compared with a suction gas plant, are as follows:

	Plant	
Heat losses.	Steam, %.	Gas, %.
In ash	2.00	1.10
Radiation and cooling	4.60	18.60
Stack gases	24.60	....
Total boiler or producer losses	31.20	19.70
Radiation and friction	3.30	4.30
Exhaust	53.50	23.70
Jacket water	....	33.50
Auxiliaries	7.30	....
Total heat losses in entire plant	95.30	81.20
Net efficiency of plant	4.70	18.80

In one of the most efficient steam plants in the country only a little over 10% of the energy in the fuel is converted into energy.

MINING IN THE FAR NORTH*

Placer Mining in the Fairbanks District

By EMIL EDWARD HURJA

Early Russian traders who penetrated to the Tanana river found the first gold in interior Alaska in the sixties and seventies. Alfred H. Brooks, of the United States Geological Survey, in making a reconnaissance of the Tanana river in 1898, suggested in a printed report that attention had better be paid to the streams entering the Tanana on the right limit as probable sources of placer gold. Following the discovery of the Fortymile placers in 1886 came the Rampart and Birch creek, or Circle, excitements, one in 1893 and the other in 1894. Prospectors from the Birch Creek district wandered across the hills into the Chatanika watershed, but their prospecting did not reveal anything to justify remaining in the district. In 1898 a party of prospectors came up the Tanana and passed the present site of Fairbanks on the Chena slough. They were not equipped with machinery for prospecting deep ground, reports Mr. Brooks, and their stay in the district yielded no appreciable results, other than to verify the presence of gold in the alluvium.

In 1901, a trading expedition from St. Michael, under E. L. Barnette, came up the Tanana, entered Chena slough and, encountering a bar, built a camp on the south side of the slough. They wintered there, and the town of Fairbanks took shape. The trading station was 275 miles from the Tanana river. In 1902, a prospector known as Felix Pedro found gold on what became known as Pedro creek in July 1902. His friends were notified, and Pedro creek and some of the outlying streams were staked. Cleary creek and Fairbanks creek became the producers of the new camp. When the news of the discoveries reached Dawson, Yukon Territory, a great rush started. Everyone stampeded. Every boat was jammed to the guards. The inevitable event in Alaskan mining camp history took place. There was no immediate bonanza and hundreds left the place, discouraged and penniless. The gravels found in the district were of low grade generally, although rich ground has since been worked on different creeks of the district. The production during the summer of 1903 was about $40,000. Conditions in the Fairbanks district—deep ground, frozen overburden, water supply, fuel abundance—led to the development of deep placer mining machinery. Powerful hoists were brought in, the 'carrier' was developed to its greatest efficiency, and systematic methods supplanted haphazard ones. Roads were built by the Alaska Road Commission from Fairbanks to the creeks, a distance of from 10 to 40 miles.

Fairbanks, though on a small slough of the Tanana river, can be reached by steamers during the season of navigation. Occasionally the water is so low that supplies have to be left at Chena, situated at the mouth of the slough, to be brought from there to Fairbanks by the Tanana Valley railroad, a development of the first five years of Fairbanks. The railroad is 45 miles long and connects Fairbanks and Chena with the numerous creek settlements on Goldstream, Engineer, Pedro, Gilmore, Dome, Vault, and Cleary. It was built by Falcon Joslin, and is considered one of the most daring projects of interior Alaska.

*[Previous articles in this series by Mr. Hurja on mining in Alaska and the Yukon have been 'Mining Revival in the Ketchikan District, Alaska,' July 4; 'Wrangell, Alaska,' special correspondence, July 11; 'Developments of the Alaska Gold Mines Co.,' July 18; 'Juneau, Alaska,' special correspondence, July 25; 'Cordova, Alaska,' special correspondence, August 8; 'Valdez and Prince William Sound,' August 15; 'Seward and the Kenai Peninsula,' August 29; 'The Koyukuk Mining District,' September 12; 'Operations of the Yukon Gold Co.,' October 10; 'Skagway-White Horse Mining District,' October 17; 'Operations of the Canadian-Klondyke G. M. Co.,' November 14; 'The Klondike, the Treadgold Placers, and Outlying Districts,' November 28; 'The Upper Yukon: Circle City, Eagle, and Woodchopper,' December 5.—EDITOR.]

LOOKING UP GOLDSTREAM, FAIRBANKS DISTRICT.

SCRAPER HANDLING GRAVEL FROM OPEN-CUT TO SLUICE-BOXES AT No. 8 BELOW, PEDRO.

The output of Fairbanks went ahead steadily. In 1904 the production was $600,000; in 1905, $6,000,000; in 1906, $9,050,300; in 1907, $8,010,000; in 1908, $9,203,000; in 1909, $9,650,000; in 1910, $6,100,000; in 1911, $5,000,000; in 1912, $4,150,000; in 1913, $4,000,000; in 1914, $3,500,000. The decrease in the output after 1909 is due to the exhaustion of the higher grade placer deposits. Some of the decrease has been made up by the lode gold production, but that industry is still in its infancy. The output of the past year is estimated at $3,500,000. The decrease is greater each year, as the ground being mined approaches the limit of workable value. Where ground averaging $1 per square foot was not touched in the earlier days, pay-dirt going 60c. per square foot is being mined today.

The chief production now is from Cleary and Pedro creeks, with Goldstream, Dome, Little Eldorado, Ester, and Vault creeks each contributing. Water was abundant this summer in Fairbanks; so much so that the bridge spanning Chena slough was washed away and several dams on different creeks were unable to withstand the floods. Not a little damage was done in and about Fairbanks during August by water. Because of the decreased production, business conditions in Fairbanks were not the best during the summer, particularly as many of the merchants stocked up with goods the year previous when a transportation rate war reduced the freight rates to a minimum.

Gust Peterson and George H. Gibbs, owners of No. 2 Below, Chatanika, are planning to do considerable work on their claim during the winter. The depth to bedrock is 140 ft.—

On the Hope claim, opposite No. 1 Below, Chatanika, Jack Brevig, Andy Brewick, and John Chater are operating a lay from the owners, Fred Schaupp and Rube Keeler. The depth to bedrock is 78 ft., of which 30 ft. is 'muck.' About five feet of dirt is taken out, including from two to four feet bedrock. The gold is coarse and assays $17.50 per ounce, as does most of the Chatanika and Cleary gold. A 40-hp. Erie boiler furnishes power for a 6¼ by 9 double-drum Lidgerwood hoist. The work from one shaft has just been finished and the other is being opened up. The pay-streak is being taken out for a distance up and downstream of 350 ft. and across the valley a distance of 150 ft. The ground averages $1 per square foot of bedrock. Sluicing started May 10. The season's output will be 60,000 sq. ft. of bedrock. Twenty-four men are employed.

The Hardscrabble claim, on the first tier, left limit, adjoining the Hope claim, is being operated by A. D. Thompson and four partners. The claim is owned by Al. Hilty, A. D. Thompson, and John Smith. The depth to bedrock is 100 ft. A new streak which parallels the one worked before along Cleary has been found. Ground 200 ft. wide and having an average value of 75c. per sq. ft. is being worked. Most of the gold is above bedrock. The summer work was fairly profitable, although the cost of working was high because of the necessity of pumping. Present plans provide for the working of a big block of ground during the winter, when the ground is frozen. The plant includes a 40-hp. boiler and a Samson hoist.

C. H. Watson operated during the summer on a big scale on the Asset fraction and Asset claim, owned by Schaupp Brothers, and situated on the left limit, opposite Discovery claim, Chatanika, and on the Hazard claim, owned by Schaupp & Keeler, as well as on the Independence claim, owned by Schaupp Brothers and Ward. Two plants are working a distance of 500 ft. apart. The depth to bedrock is 147 ft. Three feet of gravel is taken out, and from 1 to 2½ ft. of bedrock. The summer's work embraced a block 80,000 sq. ft. of bedrock. Two boilers of 25 hp. capacity operated the two double-cylinder 5½ by 8 American hoists used in hoisting. There is sufficient ground proved on the holdings to permit work to be carried on for three years more. Water is obtained from the Chatanika ditch, with a 33-ft. fall. Pole riffles in the dump-box are followed by perforated metal riffles underlain by cocoa matting to catch the fine gold. Thirty-five men are employed.

On the Hazard claim, on the left limit opposite No. 16 Below Discovery on Cleary creek, Charles Nelson, Ben Johnson, and Ole Brewick are working as laymen. The claim is owned by Fred Schaupp and Rube Keeler. A two-year lease was secured in the spring of 1914. The depth to bedrock is 100 ft.; the width of the 'pay' being worked is from 100 to 150 ft. Ten thousand square feet was worked during the summer, and plans provided for mining a much greater amount during the coming year. An 18-hp. boiler and hoisting plant are used. Gold saving is effected with pole riffles, followed by perforated metal and cocoa matting. Water is obtained from the Chatanika ditch.

John Flygar and Andrew Holmlund are operating a lay on the left limit bench claim opposite Discovery, Chatanika flats, owned by Mattson & Ward. The depth to bedrock is 50 ft. Ten thousand square feet of bedrock was cleaned during the summer, at an average value of $1 per square foot. The pay is in gravel a distance three feet above bedrock. It is 30 ft. wide. A 10-hp. boiler is used.

Probably the most scientific placer mining in the Fairbanks district is conducted by Keyes & Rettig on No. 15 Below, first tier, right limit, of Cleary creek, and the adjoining Diamond fraction. The ground was recently acquired from Hans Hess. The depth to bedrock is from 50 to 60 ft. The depth of the shaft is 62 ft. The season's work contemplated cleaning 100,000 sq. ft. of bedrock, having an average value of from 60 to 80c. per square foot. The cost of mining the ground is 50c. per square foot, according to figures kept by Mr. Keyes. Steam points are used in thawing, as is the custom generally in all

placer mines of the district, but in opening up the drifts and blocking out the ground, a novel and entirely new method was adopted. More in the nature of an experiment than anything else, an Ingersoll-Rand Jackhamer was purchased and has been used in driving holes for the sweaters. The Jackhamer drives an eight-foot hole in bedrock in 30 minutes and an eight-foot point is driven into gravel in from 15 to 20 minutes. The operation of the machine has been altered somewhat, and steam to aid in the thawing is run into the hollow point independently from a side aperture. The original plans of the machine sent the exhaust steam through the head of the point. The driving of points has formed the chief cost of opening up placer gravels, and the work of the Jackhamer has reduced this.

THREE-DRUM AMERICAN HOIST ON AL. HINTY'S CLAIM, CLEARY CREEK.

Two boilers, having a combined horse-power of 70, supply power to a 30-hp. Krogh pumping engine, an electric light plant and a 10-hp. Samson hoist. The pump is necessary to lift water into the sluice-boxes. An electric lighting plant provides lights for the underground workings and eight mine buildings. The gold lies partly in gravel and partly in bedrock. Five feet of dirt is taken out, of which 1½ ft. is bedrock. Thirty-eight men are employed. During the summer, a hoisting record was established. R. H. Keyes hoisted 287 buckets to the surface in five hours. The ten-hour day showed 526 buckets hoisted from the bottom of the shaft and dumped into the sluice-boxes. The dump-box has a length of 50 ft. In the dump-box and 50 ft. of the sluice-boxes iron-shod pole riffles are used, followed by an undercurrent of two box lengths to catch fine gold. The gold averages $17.38 per ounce.

On No. 14 Below, second tier, right limit, of Cleary creek, Kelly Brothers & Hickey are operating ground owned by W. J. Nolan and G. A. Vedin. The ground is 125 ft. deep; the 'pay' is 130 ft. wide and averages from $1.80 to $2 per square foot. The season's output is placed at 30,000 sq. ft. Water for sluicing must be raised a height of 30 ft. Two 40-hp. boilers supply power for the hoisting plant and thawing equipment. Fourteen men were employed. The lower part of the claim, 750 ft. of pay-streak, remains to be worked next season.

Alex Niemi & Co. are operating on 15 Below, third tier, right limit bench claim on Cleary, owned by G. A. Vedin. The depth to bedrock is 95 ft. The season's work embraced mining 30,000 sq. ft. of bedrock. The pay averages 70c. per sq. ft., all in gravel, with the exception of from six inches to one foot, which is in bedrock. Iron-shod riffles in the dump-boxes and sluice-boxes catch all the coarser gold, with one box of undercurrent. A 60-hp. boiler was used to operate a double-drum Lidgerwood hoist. On No. 18 Below, left limit, first tier, Hoover & Co. operated a 40-hp. plant, with a few men during the summer. Their work was said to be profitable.

Frank Johnson and John Anderson are working a lay on No. 14 Below, first tier, right limit, bench claim on Cleary. The claim is owned by Noyes & Underwood. The ground is 24 ft. deep and is frozen so that drift mining is done. The 'pay' is 100 ft. wide. Twenty thousand square feet of bedrock was cleaned during the summer. Most of the gold is in bedrock. In 1913, to take out $60,000 in gold on the claim, it cost $54,000, so closely were the expenses figured. Eighteen men are employed. A 40-hp. boiler operates a vertical Samson hoist.

Thirty thousand square feet of bedrock was cleaned up during the summer on the Snowflake bench claim, owned and operated by Peter Malone. The claim is opposite No. 13 Below, creek claim, on Cleary. Two plants are working. The 'pay' is from 90 to 130 ft. wide and averages from 60 to 65c. per sq. ft. The depth at the upper plant is 120 ft., at the lower, 134. Six feet of gravel is taken out, as no gold occurs in bedrock. An American and an O. & S. hoist are used. Two years more of operation is in sight.

O. P. Gaustad and A. C. Troseth own and operate on No. 9 and No. 10 Below, creek claims, and No. 10, right limit bench, as well as the Olnes fraction. The ground is 45 ft. deep, 11 ft. of which is 'muck.' From six to ten feet of gravel is taken out, as the gold is widely scattered above bedrock. The pay averages 50c. per square foot. The summer's work comprised 15,000 sq. ft. A No. 6 Pulsometer pump keeps the drifts free of water which seeps in from the worked out claims farther upstream. A 50-hp. Economic boiler and a 10-hp. Little Giant hoist comprise the hoisting mechanism. Fifteen men are employed. Gravity water is obtained from a ditch 1½ miles long and 400 ft. of flume-way. The dirt is dumped into a 40-ft. dump-box, with pole riffles. The sluice-boxes have perforated iron riffles underlaid with cocoa matting, which catch the fine gold. Gaustad & Troseth also own No. 2 Above, bench claim, left limit of Cleary, and the fraction between the bench and creek claim, but no work is being carried on there at this time.

H. J. Patterson is operating as layman on No. 8 Below, first tier, left limit, bench claim. The ground is owned by H. C. Hamilton. The depth to bedrock is 40 ft. Twelve thousand square feet of bedrock was to be the season's output. The 'pay' averages 75c. per square foot, and is 100 ft. wide.

KEYSTONE DRILLS USED IN PROSPECTING AT FAIRBANKS.

Gravity water is obtained from a ditch. A 30-hp. boiler operates a 6 by 8 Lidgerwood hoist. Fifteen men are employed. On No. 8 Below, first tier, right limit, owned by H. C. Hamilton and T. Treefeld, Otto Nars, Elert Hanson, and Martin Jorgenson are working a lay. The ground is 65 ft. deep. The season's work takes in an area of 24,000 sq. ft. of bedrock. A 20-hp. boiler and a 6 by 6 Little Giant hoist comprise the equipment. Eight men were employed during the summer.

Keyes & Rettig also are opening up on No. 7 Below, creek claim, Cleary. The claim has been taken under lease and option from Quinn, Gaustad, Troseth & Kern. The ground is 50 ft. deep. The pay-streak is 150 ft. wide and has been blocked out up and downstream a distance of 250 ft. The plans are to hoist all winter.

Harry Pearson and Andrew Johnson own and operate on No. 6 Below, first tier, right limit, bench and the adjacent fraction between the bench and the creek claim. The ground is 60 ft. deep. Twenty men are employed. A 50-hp. Oil City boiler and a 7 by 10 Samson upright hoist are used. Twenty thousand square feet of bedrock is given as the output for the season. Iron-sheathed wooden riffles and pipe riffles are supplemented by two boxes of undercurrent with plates and cocoa matting.

On No. 4 Below, right limit, bench claim, first tier, Wood & Piper operate a lay. The ground is owned by John Dnrand. Ten men worked during the summer, and 20,000 sq. ft. of bedrock was cleaned. The 'pay' averages 80c. per sqnare foot. It is 40 ft. to bedrock. A 40-hp. Erie boiler and a 20-hp. Harris hoist comprise the eqnipment. The ground is frozen. Gravity water is obtainable.

The first open-cut work on Cleary is being carried on by Al. Hilty on No. 1 Below, creek limit, Cleary. The upper half of the claim is owned by Hilty; the lower half by Charles Dittmer. The work of preparing the ground for open-cutting has been going on for two years. In 1912, the work of cutting a bedrock drain to keep bedrock free from water in the proposed works was started. The drain has a length of 1900 ft. It is 5 by 2½ ft. in size and is timbered and lagged for its entire length. The work of opening the ground was started on the lower end. First, a number of old tailing piles, remnants of early operations, were sluiced. The gold derived from the waste paid more than one-half the expenses of opening the cut. Then the 'muck' was ground-sluiced off where possible and scraped where necessary. An American triple-drum 3 by 10 hoisting engine, one of two of its size in interior Alaska, is operated by an 80-hp. Scotch marine high-pressure boiler. Wood used for fuel costs $14 per cord and the consumption amounts to three cords per day. A Benton electric light plant has been erected, so that work may go on continuously during the sluicing season. Most of the ground is thawed, although there are some frozen spots which have to be thawed with steam points driven from the surface. The ground has a depth of from 16 to 22 ft., of which from 4 to 12 ft. is 'muck.'

The first cut prepared is 250 by 250 ft., which was worked out during the 1914 season. Three more cuts would work out the claim. After the first cut, the waste 'muck' and gravel from successive cuts will be ground-sluiced into the worked-out cut, eliminating the necessity for expensive scraping and enabling better time to be made. Preparations have been made to obtain gravity water, with 2000 ft. of ditch and flume supplying two and one-half sluice-heads. A No. 6 Morrison centrifugal pump has been installed to return the water during the dry season. Two Bagley scrapers are in use, one with dimensions 4 by 5 by 2½ and the other measuring 3½ by 5 by 2½ ft. Each scraper is controlled from the hoist by cables, a one-inch lead line having a length of 850 ft., and a ¾-in. haul-back line having a length of 1750 ft. The cable is Roebling plow-steel and has been found entirely satisfactory. One Stevens, one home-made, and two Columbia blocks are used with the 3-ft. scraper. Six Stewart blocks are used with the 4-ft. scraper. The dirt is dumped into a hopper at one side of the cut, which empties into a dump-car having a capacity of 40 cu. ft. The dump-car is hauled up a 200-ft. incline by a 6¼ by 8 Lidgerwood hoist and emptied into the dump-box, which has a length of 82 ft. and a width of 4 ft. In the dump-box are iron-shod wooden riffles, followed by similar gold-saving equipment in the sluice-boxes, with the exception of two boxes of undercurrents. The sluice-boxes are 2 ft. wide. The cost of preparing the first cut was 50c. per square foot. Successive cuts will cost from 30 to 35c. per square foot because of the opportunity of simplifying the scraping operations.

The Hilty fraction, which lies between the Freeman bench claim and No. 1 Below, creek claim, is being worked as a drift mine because of its greater depth. On No. 7 Above, Cleary creek, just beyond the rich bonanza claims of the early days, Gust Honk, I. B. Wickstrom, and Gust Bostrom are operating on the left limit bench claim of the first tier. The ground is 56 ft. deep. Ten thousand square feet of bedrock was cleaned up during the summer and plans provide for a similar area to be worked next summer. A 30-hp. boiler and a 14-hp. American hoist comprise the equipment. The men also own No. 8 bench claim, but are doing no work on it now. Ringdahl & Co. are working on eight creek claims with a crew of four men. They have a 20-hp. plant. Westenvick Brothers are open-cutting on a small scale on No. 11 Above. David Thompson is working with two partners on 10 Above, Cleary.

The only Cleary tributaries on which placer mining is being carried on are Chatham and Wolf creeks. On Willow and Bedrock there is no placer mining. Parker & Cunningham have a small plant on No. 1 Chatham and had a few men working during the season, taking out probably $2500. A few 'snipers' worked on several of the claims farther upstream. Several discoveries were made during the summer on Wolf creek, so that there was more life there than has been evident for some years. Nelson & Sampson worked with a windlass outfit on No. 1. Schon & Larson, on the lower end of No. 1 Above, had five men working. The ground was 60 ft. deep, the 'pay' 70 ft. wide, and the season's work covered 30,000 sq. ft. A 25-hp. boiler and Little Giant hoist made up the equipment. The ground averaged from 75c. to $1 per square foot. Work will continue on this claim next year.

On upper No. 1, Bloom & Erickson took out a little gold with a windlass outfit. On the upper half of No. 2, Thynes & Co. had three men working during the summer, taking out 'pay' from a depth of 35 ft. Holk & Pierson, on No. 3, had a small prospecting plant at work hunting for a continuation of the new streak. Rasmussen & Beam had two men working on the upper end of No. 3 and took out 'pay' averaging from $4 to $5 per sq. ft., according to reliable reports. They had a 10-hp. plant. Larson & Anderson, on No. 4, had three men working with a small plant. Johnson & Co., working on No. 5 Above, found good 'pay' in shallow ground. Demos & Co., working on the Nipsic association, installed a boiler late in the season and started prospecting. Liebe & Co., on the upper part of the Nipsic association, built a plant and were prepared to work on a fair scale during the latter part of the season.

Ludwig Johnson is working on No. 15 Below, with a crew of 30 men. He has a 60-hp. plant and hoists 'pay' from a depth of 120 ft. He has lays on neighboring claims and expects to continue work for three years more. On No. 8 Below, Stewart & Co. are driving with a crew of eight men. They used a 30-hp. plant. J. H. Page is operating on No. 7 Below, with a small crew. The ground has a depth of 30 ft. Freeman & Larson, working on No. 3 Below, are opening up ground having a depth of 24 ft. They have a 30-hp. plant, employ 10 men, and expected to take out 25,000 sq. ft. of bedrock during the summer. The ground is frozen. Martin Sather & Co. operated a plant on the same claim for two months at the beginning of the sluicing season.

To be Continued

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

COPPER: DIVIDENDS DECLARED, AND RAY CONSOLIDATED, ANACONDA, OLD DOMINION AFFAIRS; AND THE EXPORT SITUATION. LEAD.

Concrete evidence of improvement in the copper situation is seen in the dividends recently declared by several of the more important companies. Utah Copper has declared its regular quarterly dividend of 75c., and Chino will pay 50c. per share on December 31. The Tennessee Copper Co. has also declared its regular quarterly dividend of 75c., payable January 2. The Old Dominion will distribute 50c. on December 31. Ray Consolidated has deferred action on its quarterly dividend. The Calumet & Hecla does not consider that the improvement in the copper situation is yet sufficiently great to justify any dividends.

There was a report in circulation that the Ray Consolidated would close on the first of January because of the Arizona law requiring 80% of mine employees to be American citizens. This has been denied by the management, which has no intention of discharging its American staff through a general shut-down. In addition, there is a good deal of doubt whether the Arizona law would be held constitutional by the courts, and also the State Department has been making representations to the Arizona state officials, since some foreign nations have already protested against a law which discriminates against their nationals.——John D. Ryan and B. B. Thayer have been in Anaconda and Great Falls recently, making plans for the future operations of the mines.——Old Dominion has been making a good recovery lately and has been showing unusually low costs, partly because the grade of the ore now being mined is higher than usual, partly because the new concentrating plant has increased recovery as well as decreased operating costs, and also because there has been a marked increase in efficiency of employees in operations generally. The November output was 1,924,000 lb. copper. Net earnings for the nine months of the year were $1,085,000, and dividends for the year will reach $1,172,000. Litigation between the Company and Mr. Hyams continues to be as involved as ever. The decision handed down by the Court of Errors and Appeals in New Jersey, which is the supreme court of that state, turns out not to be a decision, but merely a memorandum to correct an error, and further complications are still in order. For long-distance, senseless litigation, this case certainly holds the record.

The copper export problem has not much improved. It now appears that Norway and Sweden have not given guarantees satisfactory to England, as reported, and five more vessels, carrying some 6,000,000 lb. copper, consigned to Scandinavian ports, have been detained by British cruisers. The British government has made no reply as yet to the inquiry of the State Department as to whether the guarantee given by Italy is satisfactory or not. The customs officials in New York have devised a plan which they think will help the export situation, and they propose to have a customs inspector present at all times during the loading of a vessel, and when the ship clears they will issue a certificate that it has nothing on board except what is shown in its papers, this doing away with any excuse for taking the vessel into a British port to search it. But since copper is considered by England as contraband of war, this will hardly help the shippers of that metal. Exports from this country during October were 64,932,261 lb., of which over one-third was consigned to Italy. During the first 28 days of November, exports were 55,000,000 lb., only 5,000,000 lb. of which was for Italy. There is much speculation here as to whether the Copper Producers' reports will ever be resumed. Many of the producers seem to think they are productive of more harm than good, and are quite willing to let them go by the board.

The vice-president of the National Lead Co. is quoted as saying there is at present an unusual demand for lead because of the demands of neutral and warring countries, and that it is hoped to hold some of this business after the war is over. In the face of this declaration, the recent reduction in the price of lead assumes an air of mystery, even greater than usually attaches to the fluctuations of that peculiar metal.

The statement in last week's notes that Hayden, Stone & Co. had purchased the Butte-Duluth mine is denied by that firm. [The information came to us so direct that it seemed unnecessary in this case to confirm it by appeal to Hayden-Stone. Correction is made elsewhere.—EDITOR.]

TORONTO, ONTARIO

CANADIAN NICKEL, THE UNITED STATES, ENGLAND, AND GERMANY. —GOLD MINING AND SHARES.—RESUMPTION OF ANTIMONY MINING.

The agitation connected with the export of nickel to the United States, with the possibility of the refined metal reaching Germany, has subsided, as a result of recent action by the Canadian government, which has for some time been in communication with the British authorities on the subject. The International Nickel Co., of New Jersey, to which the nickel matte is shipped for refining, claims that it has em-

AN AVERAGE SILVER SHIPMENT FROM THE BUFFALO MINE, COBALT; 141 BARS, 140,544 OZ., 999 FINE, VALUED AT $81,325.

ployed effective measures to prevent any of the output being sent to Germany by an indirect route, and invited investigation. Accordingly, an accountant was sent to New York by the Dominion authorities, who made a careful investigation. His report, which is said to be satisfactory, has been sent to the British government, and its decision will, of course, determine whether the Canadian people should take any further action or not. Meantime, it is not considered at all likely that the export to the United States will be interfered with, as it would be a very serious blow to the mining in-

dustry. Production at the mines of the Canadian Copper Co. has been steadily increasing of late, and is now stated to be about normal. The Mond Nickel Co., the output of which all goes to England, is preparing to make important extensions to its plant, the funds for which will be raised by an issue of £500,000 6% redeemable debenture stock.

Since the resumption of trading in mining stocks, the market has been quite active, especially in Porcupine issues, owing to a confident feeling that the gold mining industry is about to enter on a period of prosperity. The re-entry into the field of the Bewick, Moreing & Co. interests of London, whose Canadian company, the Northern Ontario Exploration Co., is preparing to resume active development work on its holdings, is regarded as a significant indication of the greater interest likely to be taken in the district by British financiers. The great demand for gold created by the war naturally directs attention to the goldfields, and further investments are looked for. The main drawback, however, is the exorbitant prices at which improved prospects are held by the owners, which have all along acted as a deterrent to the more rapid development of the country. Trading in the Teck-Hughes, in particular, has been active, owing to the recent opening of an ore-shoot said to assay $28 per ton over a good width.

The demand for antimony, which is used in the manufacture of shrapnel, and the cutting off of the supply from Germany, has resulted in the reopening of the antimony mines at Lake George, York county, New Brunswick. These were worked many years ago by the Lake George Mining & Smelting Co., with an output of about one ton per week, and afterward by the Canadian Antimony Co., but operations ceased owing to the low price of the metal and the distance from railway facilities. The price has now risen to 14c. per pound, and the transportation difficulty has been solved by the completion of the St. John Valley Railroad to within three miles of the plant, so that there seems to be a fair opportunity for putting this industry on a permanent basis.

PLATTEVILLE, WISCONSIN

Blende, Galena, Iron Pyrite, Carbonate of Zinc during November.—Ochre Mining.—Production by Districts.

November brought to light no unusual developments in the way of production and ore deliveries in the zinc-lead districts. The metal markets at the beginning of the month offered little encouragement to an increased output, spelter being quoted at $4.75 to $4.85 per cwt., St. Louis. Gradual and substantial gains were recorded, forcing the price above $5, the month closing at $5.35. With this advance in the price of metal came also a more marked advance in the price of blende, and the base was raised from $39 to $43, to $43 to $47 per ton, 60% grade, which prevailed in the closing days of the month. With low prices, however, marked increases in production of raw concentrates were noticeable, with corresponding gains in deliveries. This situation was entirely reversed at the end of the month, the production of raw zinc concentrates the last week being just half that recorded in the first two weeks. The only reasonable conclusion that could be arrived at seems to be that producers, scenting still higher advances in both the price of metal and ore, had concluded that a waiting game might prove the more profitable. All the active producers are in better shape than ever to make a heavy recovery, weather and road conditions could not possibly have been better, and labor was in good demand, so that a curtailed production could in no wise be charged to any of these ulterior causes. The reserve in the field at the close of the month was conservatively estimated at less than 3000 tons. Buyers were active in all the districts, and competition was more accentuated than at any time previously during the year. Leading buyers representing Eastern mining syndicates freely predicted $5.75 to $6 for spelter at the beginning of the coming year, and $50 per ton for blende.

Lead ore ruled weak the first half of the month. Prices were slightly in advance of $40 per ton; then a radical change became effective. A better demand was in evidence and prices advanced sharply until bids recorded $48 per ton, in the last days on 80% ore. Miners regarded the gains askance and held their ore closely, shipments for the entire month being exceedingly light.

Producers of iron pyrite met with poor demand, and sagging quotations, and production was greatly curtailed. Deliveries were light and confined principally to the Benton district.

Producers of carbonate zinc ore, operating in the northern districts of the field, met with a sporadic demand in the beginning of the month, which was totally absent at the end. The price based on calamine ores for the Missouri product is good, giving the Wisconsin miner about $12 to $16 per ton for his product, most of which is taken in the dry and economically mined. Shipments were light, and a heavy tonnage was carried over. Production has not been diminished, as the small concerns are all operating underground again for the winter.

What promises to develop into a new industry in this field is found in the shipment of a car of ochre from the Highland district which brought $5 per ton. This mineral is to be used in the manufacture of paint, and on experiments now being conducted by a large paint-manufacturing concern depends the mining of the ochre in large quantities. Deposits 15 ft. thick and of large tonnage are found in the northern districts of the field. An experiment of this character was tried once before, many years ago, but the great development of the Middle West makes the carrying out of a project of this kind more feasible at this time.

Zinc ore deliveries were made from the districts of the field during November as shown in the table herewith:

Districts.	Zinc, pounds.	Lead, pounds.	Pyrite, pounds.
Benton	6,542,000	262,400	1,814,020
Galena	5,268,000	.....	.....
Cuba	4,114,000	.....	.....
Hazel Green	3,520,000	220,000	.....

Total	29,186,000	602,700	1,814,020

SYDNEY, NOVA SCOTIA

Timber for English Mines.—Coal Production.—Gold, Tungsten, Gypsum, and Oil Development.

There is unusual activity in procuring 'pit props' for the mines of Great Britain throughout the maritime provinces of Canada and Newfoundland. England's supply of mining timber formerly came from Norway and Sweden and other contiguous countries which are now partly or wholly cut off from transportation. New Brunswick, which has extensive forests, is especially profiting by the business; but ships are picking up the timber from piles all along the east coast of Canada, where men thrown out of employment from other lines are cutting the props on contract or for wages.

There is reason to believe that the war will benefit the coal mines of Nova Scotia, on account of the demand for bunker coal for warships, which are taking increasing amounts of Welsh and Continental coal, so that Nova Scotia

may get some of the export trade that these countries formerly took care of, in spite of dull times in many manufacturing lines in eastern Canada. The coal mines of Nova Scotia, particularly of the Sydney district, are more extensive and important than is generally appreciated. The production of coal in Nova Scotia has grown from about 3,000,000 tons per year in 1900, to 7,000,000 tons for the year 1913, and gives employment to over 12,000 men; an output of over 500 tons per man per year. Most of the mines are within a few miles of an Atlantic port with which they are connected by railroads. The industry is in the hands of a few large companies, such as the Dominion Coal Co. and Nova Scotia Steel & Coal Co. Vertical shafts as well as incline slopes are used. About one-third of the province's coal output is consumed within itself, where the Dominion and Nova Scotia companies have iron furnaces and steel works. These in 1913 used 900,000 tons of imported iron ore, mostly from Newfoundland. Another third of the coal goes to the province of Quebec, while the remainder is shipped to other maritime provinces and to the United States, the last-mentioned taking 500,000 tons of Nova Scotia coal yearly.

Other mining industries in Nova Scotia include gold, tungsten, and gypsum. The gold mines have dwindled in production of late years, although several hopeful operators are endeavoring to apply modern close methods of gold saving, by improved cyanide treatment, to ore from the rather narrow quartz veins. Nova Scotia has been producing gold for over 50 years. In several periods the production has risen to over 25,000 oz. per year, the last time from 1896 to 1903, but in 1913 the output was only 2364 oz. There are no large deposits, at least so far discovered, but there are a number of small mines and prospects scattered throughout the province. Tungsten mining in Nova Scotia, which attracted some attention recently, has been disappointing, although an amount of shaft-sinking and driving was done in the hope of establishing a new industry. Gypsum mining, or quarrying, is represented by several companies, which in 1913 produced 270,000 tons, much of which was shipped to New York, to be used for plaster.

In New Brunswick some little excitement was aroused in the past two years by extensive drilling for oil along a belt not far from the ocean. A little was found, but more gas. Iron mining during recent years has not been successful. However, ore of fair quality is known to occur in the district back of Bathurst, and will some day become important.

PETROGRAD, RUSSIA

RÉSUMÉ OF THE RUSSIAN GOLD-MINING INDUSTRY: LABOR SHORTAGE, WAGES, DREDGING PROSPECTS, AND COMPANY OPERATION IN PLACE OF SMALL CONCERNS.

The position of gold mining in Russia this year, never particularly promising, is naturally less so now owing to interference with the labor market by the opening of hostilities, and consequent mobilization of military forces. A semi-official report on the prospects of this year's gold-mining returns observes that it has not promised to be very active, and that quite independent of the military question, the most serious obstacles to its further development lies in the shortage of labor. This factor in the industry is growing increasingly difficult on account of its cost. Labor in Russia grows persistently dearer, and to add to this difficulty there is the recognized impoverishment of the gold deposits that have hitherto been worked and which has resulted in the shutting down in many cases, particularly in those of the smaller industrialists, of their operations altogether, though in others they have only curtailed their work.

Taking Western Siberia under particular observation, and the Orenburg mining district, there is no doubt that the activity of the operators has considerably declined simply because of the scarcity of labor. This is directly attributed to the construction of railways, which attracts nearly all the workers, and consequently makes the cost of such as are willing to remain in the goldfields almost prohibitively high.

This incubus, so to speak, on the gold industry was not naturally foreseen when, in response to the demands of the operators themselves, the government started out on an active railway construction campaign, which has the temporary effect referred to, but will no doubt in the future have its recompense in the form of easier access to the consumers' markets for the products of the mines.

It is in the Amur district, however, that the weight of this consideration is being most seriously felt, because of the prohibition by the government against the employment of yellow labor in the gold mines; and it is feared that the direct result of this policy being put into effective force will be to bring about a disaster to the gold industry in the Amur territories. While the daily wages of the Chinese and the

.....RAILWAYS. ..... BOUNDARIES.

PART OF THE RUSSIAN EMPIRE.

Koreans can be reckoned at 70 *kopeks* (35c.), the daily wage of the Russian workman varies between 2 *rubles* and 2 *rubles* 75 *kopeks* ($1 to $1.38). Even on such terms, the demand for the Russian workmen is heavy, and the gold producers are taking all measures in order to keep such in their mines for some special work such as investigation of areas, carpentry, and metal work, etc. At the same time, it must be remembered that many deposits recently exploited have not paid even with cheap yellow labor.

Generally in the Russian gold industry there is observed the rise of strong concerns, and a gradual disappearance of the smaller ones. This is explained chiefly by the low-grade nature of the gold-bearing deposits. The richer gravels, as has so frequently been noted, have been worked out, while the poorer ones require the application of newer and more expensive machines, to obtain which the smaller producers have not the means.

One of the most improved methods for operating in the goldfields is the dredge, which makes it possible to exploit low-grade ground. The application of the dredge in the Yenesei jungle has resuscitated altogether the recovery of gold

from this old district. Unfortunately, the development of the dredge business in Russia is seriously hindered by the absence of works for their construction. The Putiloff factory, which has a special dredge department, scarcely handles them at all; it being chiefly occupied in filling orders for the war department. The Neviansky factory, which constructed boats consisting to the extent of about half, of imported parts, has also completely ceased building them of late. As to the foreign manufactures, the cessation of the duty-free importation of machine parts in 1909 has made their use entirely too expensive for the exploitation of Russian gravel. But notwithstanding these obstacles, the dredge business in Russia continues to develop. Among others, there is the Orsk company, which has converted the old stacker scow into an electrically operated boat.

Attention must be called to the growing interest of foreign capitalists in the Russian gold-mining industry. Several large English companies, with a capital of several millions, have, as is known, leased considerable tracts of land from the Imperial Cabinet. These areas, in spite of their considerable richness, have hitherto remained unexploited because they require the application of complicated and expensive equipment. Many other English companies that have taken an interest in such lands have been sending commissions this year into the district referred to, for the purpose of becoming acquainted with the industrial and mercantile value of deposits therein.

Respecting new gold regions, attention is directed to the northeastern portion of Siberia, and to the coast of the Okotsk sea, where gravel has been discovered which contains a fair percentage of gold. One company that has only been partly formed has sent an engineer to these areas for a closer examination of their value.

An encouraging note in the semi-official report deals with the discovery of gold deposits on the lands of the Lena company in the River Bodaibo district. This is considered to be of much importance. There is intensive prospecting being done throughout the Lena basin. The Olekminsk Gold Co. is sending an expedition to the Charu river, and another away to investigate the zone of the River Tartygi. The chief object of these expeditions is to find out whether it is possible to use dredges. Naturally, these reports are awaited with considerable interest, because if the answer is affirmative it opens a new future for this Lena basin in which the dredging hitherto has not been applied. At the same time, these expeditions will inquire into the navigation possibilities of the rivers that serve the district.

KALGOORLIE, WESTERN AUSTRALIA

LABOR IN POLITICS AND THE MINING INDUSTRY.—THE NEW MINE, THE EDNA MAY.—NEW GAS PRODUCER.—SONS OF GWALIA MINE.

The result of the state elections has been a distinct setback to the Labor party, and should put an end to its extreme and socialistic legislation for the time being. The premier, John Scaddan, when stumping the country before the elections, stated that when returned to power, he would reintroduce his 'war' tax, imposing a duty ranging from 1 to 15% on all incomes, apart from the current tax of 5% on dividends. He also threatened the re-imposition of the new Mines Regulation bill, to abolish night shift, contract and bonus work, to reduce a working week to 44 hours, to reduce the number of foreigners to 1 in 10, to give preference to unionists, to double wages for Sunday work, and to inflict numberless other disabilities on the mining industry. As Mr. Scaddan's majority in the Legislative assembly will be two, at the most, and his party is in a hopeless minority in the Legislative Council, his power for mischief is reduced to zero. In fact, neither party will be in a position to pass any legislation of a controversial nature, and it will be a case of mark time for the next three years.

The lode in the Edna May at Westonia, 42 miles west of Southern Cross, and only 195 miles east of Perth, has straightened up from 1 in 1 down to 75 ft., to 1 in 3 between 150 ft. at 225 ft., and the outlook has considerably improved. The second granite bar, 8 ft. thick, was cut in the shaft at a depth of 201 ft., and was passed through in the cross-cut at 68 ft., and until the next level is opened its effect on the lode will not be known. At the 225-ft. level the lode is 25 ft. wide, and assays $40.80 per ton. The drift, at 225 ft., for the first 50 ft. driven on the hanging wall side, assays $33.80, for a width of 12 ft., with ore still on the foot-wall. Up to the end of September the output has been 30,715 tons for $658,650, and dividends aggregating $299,900 have been paid on a nominal capital of $107,100, of which only $41,250 was cash. Owing to the influx of water, an 8-in. Cornish lift is now being installed, and when it is completed, sinking will be resumed. A large number of adjoining leases is being worked, but so far as tested, none of them is any good. The Edna May lode, like the Great Fingall, Golden Pole, and Bullfinch, is confined to a break in the country, outside of which nothing of any value can be located.

A new down-draught wood-gas generator has been invented by G. H. Allen of Fremantle, which, according to I. C. Davies, manager of the State Implement Works, is better than any generator now in use. In fact, Mr. Davies asserts that the Allen generator is driving a 200-hp. gas engine, fully loaded, on half a ton of firewood, against 2 tons consumed by a generator installed only last year. Until the invention is further tested, and fuller particulars are available, it is premature to speculate as to its effect on the mining industry. Mr. Davies states "that the gas produced is absolutely free from all impurities," a rather large statement to make.

The attempt to find a profitable ore-shoot to the north of the main shaft in the Sons of Gwalia mine has so far proved unsuccessful. Owing to the intrusion of epidiorite having cut out the gold in the south end of the mine at No. 17 and 18 levels, Malcolm Maclaren advised prospecting for a new shoot to the north. A shaft was accordingly sunk 1000 ft. north and, at a depth of 80 ft., a good deal of cross-cutting and driving has been done, unfortunately with negative results. Since alterations and extensions to the treatment plant were started two years ago, $297,600 have been spent on equipment. The result has been that costs have been reduced from $5.56 to $5.16 per ton, and profits increased from $2 to $2.30 per ton. Now that the plant is in full swing, and the large expenditure on capital account completed, the dividend which, for last quarter, was cut down to 12c. per share will probably be raised again to 24c. The ore-shoot at No. 20 level, so far as tested, averages $21 per ton.

The state's gold yield in September was worth $2,232,500, and dividends paid amounted to $512,600. There were few changes in the monthly returns. In October the output was $2,153,460, and dividends $299,600. Of this the Edna May yielded $70,700 from 2907 tons, worth $49,100 profit, paying $32,100 in dividends.

The present position of the gold-mining industry is adversely affected owing to the increase in price of stores due to the war, and to the difficulty of obtaining fresh capital while the war lasts.

A scheme for ameliorating the lot of miners who have been injured by accidents or disease caused during their work, has just been formulated, and should be beneficial. The annual amount of money at the disposal of the executive is estimated at $125,000, of which the workmen and mine-owners subscribe 25% each, and a government subsidy makes up the balance.

At 2900 ft. in the Horse-Shoe, the north drift at 122 ft. averaged $59.92 per ton over 8 ft.—The Ivanhoe main shaft is down over 3200 feet.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Since systematic work was begun by the U. S. Geological Survey in exploring and mapping the mineral resources of Alaska, in 1898, the Survey has covered by exploratory geologic surveys 72,000 square miles, by reconnaissance geologic surveys, 96,000 square miles, and by detailed geologic surveys, 4071 square miles. During the same period topographic exploratory surveys have covered 51,000 square miles, topographic reconnaissance surveys 116,000 square miles, and detailed topographic surveys 3642 square miles, according to the thirty-fifth annual report of the director of the Survey.

Cordova

Tests of the Matanuska coal on the cruiser *Maryland* are reported to have been quite satisfactory.

Juneau

The Alaska Treadwell company is cutting out a new shaft in the Ready Bullion mine by rising from the 2200-ft. level, and will also sink it 200 ft. below that level. From 70 ft. to the surface has been holed through, and rising is to be started next at 450 ft. The shaft is 7 ft. 8 in. by 20 ft. outside, with four compartments, and inclined at 70°. The collar will be of concrete, and the hoist driven by electric power.

At the Alaska Gold Mines' property all of the underground driving that has been planned for some time to come is practically finished. Work is now chiefly confined to the details

ALASKA GASTINEAU SHOPS AND YARDS, FROM THE COARSE-CRUSHING PLANT.

of cutting out stopes, putting in manways, ore rises, etc., with a view to having the mine fully prepared to furnish the large tonnage that the mill will call for. Electrifying of the Sheep Creek tunnel is under way, electricians being engaged in stringing both trolleys and feeders all the way from the coarse-crushing plant through the tunnel to the main ore-way. At the power supply division the work is entirely operative, and the two power houses are now supplying the power necessary for all the requirements at both the mine and the mill. At the reservoir, the water his risen to a height of 132 ft., equivalent to 12,600 acre-feet. The average gain of the reservoir over what is used is a little over 600 acre-feet per week. The water-power being developed here is in excess of the estimate. At the reduction division, the coarse-crushing plant is completed, with the exception of the tipple, and parts for this have arrived. The power cables from the substation to the coarse-crushing plant will be completed within a few days. The ore-pocket is finished. At the main concentrating plant the steel erectors have finished their work, and setting of the rolls has been commenced. Both upper and lower floors for the Wilfley and Garfield tables have been cast. This completes all the floor work in the west sections of the mill with some slight exceptions. The mills and tables are either en route or have arrived.

An Ingersoll-Rand 40-drill compressor is being installed at the Alaska Juneau mine. It will be electrically driven.

ARIZONA

Gila County

The Old Dominion mine produced 1,924,000 lb. of copper in November, against 1,616,000 in October, and 2,962,000 lb. in July.

The Superior & Boston Copper Co. reports as follows for the year ended September 30, 1914: Ore shipments were stopped in August, owing to the copper situation; but development, which amounted to 4424 ft., and 563 ft. of diamond-drilling, shows a promising future. This was especially so at 800 and 1000 ft. east from the Quo Vadis fault. Rocks of the contact near the vein are diabase hanging and lime footwall. Work at present is at 800 ft., expenditure being limited to about $2000 per month. The great flow of water in the mine interferes with work, but water-level has been lowered to below 800 ft. Ore shipped was 25,625 tons, realizing $291,515, against $153,436 in 1913. All expenses totaled $309,218, and the deficit was $15,982. The cash balance is $59,286.

Graham County

For the third quarter of 1914 the Shannon Copper Co. reports that its output was 2,064,767 lb., and net earnings $26,562, compared with 3,118,156 lb. and $40,951 in the previous quarter. The cost of producing copper was 11.36c. per pound.

CALIFORNIA

Amador County

The preliminary report of the superintendent, James F. Parks, of the Plymouth Consolidated, shows the following results for November:

Ore crushed, tons	9900
Gross value of output	$42,982
Average per ton	$4.34
Working expenses	$23,884
Cost per ton	$2.41
Development charges	$4013
Cost per ton	$0.405
Surplus over working and development	$15,085
Other capital expenditure	$10,180

Butte County

In the suit of the Leland Stanford University trustees *v.* the Butte Creek Consolidated Gold Dredging Co., Judge McDaniel, at Oroville, has granted a preliminary injunction against the Company. This will prevent the boat from working in Butte creek. The Company testified that it was being moved and was not digging within 50 ft. of the present channel.

A 42-oz. gold nugget was found on Butte creek, near Nimshew, by E. J. Deneen, on December 11.

SAN BERNARDINO COUNTY

At the annual meeting of the Consolidated Gold Fields of South Africa, held in London recently, the chairman of directors said that in one respect it is particularly disappointing that he was not able, as had been anticipated, to tell shareholders that potash was being supplied to the market by the Trona Corporation, operating at Searles lake, California. He had fully expected from the reports and statements of the engineers that he would be able to do so at this meeting, and as, owing to the war, the United States has been deprived to a considerable extent, possibly entirely, of its supply of potash from German sources, it would, of course, have been a distinct advantage if the Company could have been in the market under such favorable circumstances. That potash, borax, and soda ash can be produced on a large scale has been demonstrated by actual figures, but the accuracy of the estimates as to the working costs and yield can only be definitely tested by operating on a commercial basis the fully equipped unit of the plant, which the directors are assured will be during next January. The margin of profit under normal circumstances has always been a good one, but since estimates were made this margin has largely increased owing, it may be, to the cessation of imports into America, which may not be resumed for many years.

SHASTA COUNTY

Forty members of the Shasta County Farmers' Protective Association have sworn that they do not suffer from smelter smoke, and 15 others state that they are plaintiffs in the Mammoth suit without their consent.

SIERRA COUNTY

An 180 gal. per minute centrifugal pump is being installed at the Telegraph mine, and sinking is to be resumed later. H. V. Hughes is superintendent.——Twenty stamps are crushing ore at the Monarch Consolidated, and developments are good.——The Oakland quartz mine has been sold by F. B. Voyle to F. A. Gowing of Oakland.

TUOLUMNE COUNTY

(Special Correspondence.)—The Eleanor Mining Co., Inc., is finishing development work on the Blue Eagle and Little Jawbone claims, which are situated on the north bank of the Tuolumne river, about 800 ft. from the same, and 1200 ft. east of Jawbone creek, in what is known as the Jawbone mining district. The outcrops on the Blue Eagle indicate a large orebody. The vein is exposed to a height of 80 ft. before it dips into the mountain, over 50 ft. across the top, and it is approximately 18 ft. wide. The ore is rather unusual for this locality and contains about 10% of sulphides, pyrite, pyrrhotite, and chalcopyrite. A large number of tests proved that the ore is amenable to concentration and cyanidation, with a high extraction. Up to the present time, four adits have been started to open the mine. The orebody developed is estimated to contain 12,000 tons averaging about $10 gold per ton. Ore of the Little Jawbone is of a similar nature and average value. The vein is 4 ft. wide. The Company has now installed a gasoline engine and air-compressor and drills, and is pushing development as fast as possible. A 50-ton mill will be built next spring.

As there are a number of other good claims in close proximity which this Company is now negotiating to secure, this locality will make a large field for mining operations. The mill will be operated by water-power, of which there is an ample supply from Jawbone creek. M. L. Crafts, formerly general manager of the General Custer mine of Custer, Idaho, and assistant superintendent of the Anaconda mine under Marcus Daly, is in charge of the mines.

Oakland, December 7.

The gravel deposit near Sonora owned by the Peoria Flat Mining Co. has been drained. A steam-shovel is being installed to dig the material and deliver it to a Querner reduction machine.

COLORADO

CLEAR CREEK COUNTY

The Waldorf mine, near Georgetown, is producing a good tonnage of smelting ore, and concentrate from its mill. The Herber lease is yielding high-grade ore from the Commonwealth vein at 300 ft. A cyanide plant is proposed for next spring.——The Josephine, in West Argentine, has suspended on account of the low price of lead.

GUNNISON COUNTY

The Quartz Creek district, near Pitkin, is more active lately on account of recent developments. A fine body of copper ore has been cut by the James Harbaugh Co. at the base of Siegel mountain. Rich gold ore was opened in the Buffalo Head, five miles from Pitkin. A 3-in. streak containing some bismuth occurs next to the vein. The new Camp Bird shaft is down 50 ft., and an electric hoist is being installed.

LAKE COUNTY (LEADVILLE)

The new Davis shaft in the Fryer Hill district is through the overburden at 115 ft., and is in mineralized porphyry.——After several years' idleness the Little Bob mine is being reopened. Men are cutting ice from the shaft and doing preliminary work.——Sinking of the Monarch shaft, and driving an adit into Prospect mountain, in the South Evans district, in which is the Little Bob and others, will help considerably to develop this territory.——The Big Four new tramway is in operation.——Some rich silver ore has been opened in the Double Decker on Yankee hill.

SUMMIT COUNTY

The Wellington Mines Co. at Breckenridge is operating both its mills full time and is shipping 7 to 8 cars of zinc concentrate per week to Bartlesville, Oklahoma.——The French Gulch company's dredge is producing from $25,000 to $31,000 per month. Steam is being used for heating purposes. A carload of iron-lead sand accumulated from the sluices, and this has been sent to a smelter. Herman J. Reiling is manager.——The Tonopah Placers boats are still working, and No. 3 may continue through the winter.

TELLER COUNTY (CRIPPLE CREEK)

Three large transformers are being installed at the Vindicator. The mill is working full time. No. 2 shaft has been retimbered.——The 12-ft. orebody recently found in the Mary McKinney is giving high assays. Lessees in the Howard shaft are mining 3 ft. of $40 ore.——Four or five feet of $30 ore is being shipped from the Monument claim, near the Ajax, by Ross and Cammenish.——Fish and Harris in the Portland have opened 100 ft. of ore averaging $25 per ton over 3 ft. width.——Fifteen lessees are now shipping a good tonnage of three grades of ore from the Granite mine on Bull hill.——A very rich shoot has been opened at 1200-ft. in the Cresson mine, and a carload of ore variously estimated to be worth $400,000 to $1,000,000, has been sent to Denver.

IDAHO

SHOSHONE COUNTY (COEUR D'ALENE)

The Federal company has given up its bond on the Star claims, adjoining the Morning mine. Ore was not found in quantities expected, and the low price of lead influenced the decision also. Spokane people, the Finch & Campbell syndicate and others, and E. H. Moffitt of Wallace own the Star property, and will drive a new lower adit from 2500 to 3000 ft. to cut the veins. These mining men also have an interest in other properties in this district.——The Independence claims have been sold to J. P. Mahoney, of Wallace, by the receiver for $20,475. The New Independence Mining Co. has been formed to work the property. H. L. Day, of the Federal, is largely interested in the deal.——Good progress is being made in extending the transmission wires of the Montana Power Co. The line is 32 miles long, and men are string-

ing wires into Burke and Mullan. A lively power war is expected between this Company and the Washington Water Power Co., now supplying current.——The orebody in the Nabob, on Pine creek, has widened to five feet, part of which is clean shipping galena.——A new Nordberg hoist has arrived at Burke for the Marsh mine. The new three-compartment shaft is finished and connects the orebody at 800 ft. with the adit. The shaft will be sunk a further 275 ft. A large underground station has been cut, and the new hoist, driven by a 300-hp. motor, is to work there. It will raise 2½ tons per trip from a depth of 2700 feet.

MICHIGAN

HOUGHTON COUNTY (THE COPPER COUNTRY)

The report of the Old Colony Copper Co. for the year ended October 1, 1914, shows that the revenue from assessments, etc., was $105,875, of which $34,840 was spent in diamond-drilling, and $14,063 in taxes and general expenses. The balance on hand is $56,971. The superintendent, George S. Goodale, reported that the drills did 12,774 ft. of work in eight holes. No. 26 hole developed the Mayflower lode between 1749 and 1826 ft., No. 27 proved it from 1796 to 1828 ft., No. 28 from 1675 to 1705 ft., No. 29 from 1681 to 1692 ft., No. 30 from 1764 to 1863 ft., No. 31 from 1810 to 1844 ft., and No. 32 from 1780 to 1826 ft., while No. 33 has not yet cut the lode. Progress was satisfactory.

A large piece of 'mass' copper has been exposed in the Trimountain. It extends from above No. 25 to No. 27 level. Miners call it a fissure instead of a mass.

(Special Correspondence.)—Total shipments of iron ore from Duluth for the season closing December 1 amounted to 32,020,487 tons. This is the smallest movement since 1908, when the total was 25,427,094 tons.——The agreement between

DRILLING WITH SPIRAL STEEL AND A SULLIVAN DRILL IN ONE OF THE SOFT IRON ORE MINES OF THE LAKE SUPERIOR REGION.

the Great Northern and the United States Steel Corporation will end January 1. The former will operate its own ore properties which have estimated deposits of 200,000,000 to 300,000,000 tons, and M. A. Hanna & Co., of Cleveland, Ohio, will act as selling agents.

Houghton, December 12.

MISSOURI

JASPER COUNTY

Fourteen districts contributed toward making the past week an unusual one in point of the great number of companies represented, the total having been 118, Joplin being the leading district with 30 companies, Webb city next with 27, while a few of the other large areas showed the following: Alba-Neck City, 6; Duenweg, 7; Miami, 10; Galena, 14; Spring City, 8; Carl Junction, 4; and Belville, 3. As a number of large tracts of land are included in the total number of companies, the actual number of producing mines would be materially in excess of the 118 given. Cold weather is causing the closing of a number of small mines in the district.

A 300-ton mill is under construction for the Jasper County Land & Mining Co. on the Connor land, south of Carterville. Three mills are now working in this sheet-ground area, and within a few months there will be five. Ore is found at from 190 to 210 feet.

MONTANA

FERGUS COUNTY

Gold yield of the Barnes-King Development Co. in November was $41,000, from 5035 tons of ore, compared with $31,900 and 3955 tons in October.

SILVERBOW COUNTY

The Anaconda company is to extend its operations in Montana by the expenditure of several million dollars.——It is expected that the Butte & Superior mine and mill will resume operations during the last week of December.

NEVADA

CLARK COUNTY

The Boss mine in the Goodsprings district has been sold to a syndicate headed by W. C. Price, of Los Angeles, Mr. Pelchler of Sacramento, and H. Fleischaker of San Francisco. A deposit of $50,000 has been made at Las Vegas, and on further payment of $100,000 the property will pass to the Gold-Platinum Mining Co., now being organized under the laws of Arizona, with a capital of $1,000,000.

ELKO COUNTY

Lessees in the Nevada-Anaconda property, 12 miles north of Carlin, have completed about $10,000 worth of development. Adits have proved a vein of 2% copper ore, and a well defined vein of lead carbonate ore. Several carloads have been sent to smelters. The Company will drive a deeper adit to cut these lodes. Henry Lewis is in charge.

ESMERALDA COUNTY

At 1750 ft. in the Union Jack claim of the Atlanta property, near the latite-shale contact, 5½ ft. of ore has been opened for over 20 ft. It contains up to $40 per ton in gold and copper. The Company has $30,000 in its treasury.——To further open its new shoot in the Velvet claim, the Jumbo Extension is extending the east cross-cut at 1017 ft. a distance of 60 ft. A third rise will be driven to the latite-shale contact.——After a suspension of several years, work has been resumed at the Commonwealth. The shaft is to be sunk from 300 ft. to 700 ft., to cut the latite-shale area.

EUREKA COUNTY

The Cortez Mining & Reduction Co. is operating in the Cortez district. The ore mainly contains silver and lead, with some gold, zinc, and iron. Up to the early part of August the mill was treating from 1500 to 1800 tons of ore, producing a silver-lead concentrate. A large body of lower-grade silver-lead ore, but higher in gold, has been developed, and the Company is investigating processes to treat the concentrate produced.

HUMBOLDT COUNTY

The Antelope Springs Mining Co. is operating in the An-

telope Springs district, John W. Geiger being general manager. The mine has been developed by adits, No. 4 being in 1300 ft. At 844 ft. vein formation was cut, and driven on for 300 ft., when No. 1 ore-shoot was found. This has been opened 40 ft., and is from 4 to 20 ft. wide, containing silver, lead, and zinc. The mine contains 4000 ft. of workings. The nearest shipping point is 20 miles away. It is now proposed to build a mill to treat the ore, and the manager and other officials are in Park City, Utah, investigating the Daly-Judge mill, which is dealing with similar ore. The proposed plant will cost about $100,000.

NYE COUNTY

Tonopah mines produced 9381 tons of ore, worth $194,818, last week.——The Jim Butler-West End suit is reported to be making good progress.——The Tonopah Mining Co. has secured a lease, and option to purchase within two years, of the Mizpah Extension property. The latter owners get 50% of the net profits of ore mined during the period. If the option is exercised, a new company is to be formed with a capital of $5,000,000, of which the Mizpah Extension gets $2,000,000 and representation on the directorship. The Extension will pay three dividends of 2½c. per share each on January 1, an ordinary, an extra, and a special, totaling $76,750.——Development in the Montana continues encouraging.

The Eureka Johnnie Gold Mining Co. is operating at Johnnie, in charge of Charles Labbe. Several thousand tons of fair grade ore has been developed. A new vein was cut last week, showing 4 ft. of $25 ore. The quartz veins occur in sedimentary formation. The property is fully equipped, and a small mill is contemplated.

Traces of platinum have been reported from this district, which is a promising one, and needs a custom mill.

STOREY COUNTY

The old International hotel at Virginia City, built in 1876, and with many associations of the life of the Comstock Lode, was destroyed by fire on December 12.

WHITE PINE COUNTY

The Nevada Consolidated company's *Safety First* for November shows that there were 12 minor accidents at the property. There was one fatality at the smelter, when a switchman was riding in the cab of a dinkey locomotive which was running backward with an empty slag pot. He was sitting facing forward, and somehow fell face foremost on the track, and was run over. He apparently had not hold of anything, hand-holds being provided.

It is expected in Ely that work will be resumed at the Copper Mines company's property, and drilling at the Giroux.

NEW MEXICO

DONA ANA COUNTY

(Special Correspondence.)—Reports from Rincon state that the discovery of high-grade gold ore in the Caballo mountains was a 'gold brick' scheme, the samples being salted. The Riverview Mining & Development Co. was organized and incorporated for $10,000 to work the properties, claimholders near the 'strike' pooling their holdings and putting in $5000 each toward development. Clyde M. Becker, living at Rincon, states that the gold found in the assay pulp was placer gold, and the copper had been injected from a small high-grade copper vein near the mine, and corrects previous reports given out as to the Caballo mountain 'high grade.'

Rincon, December 1.

GRANT COUNTY

(Special Correspondence.)—The White Signal mining district, south of the Burro mountains, is coming into prominence, and activity in the region is greater than it has been for some time. The lower transportation costs made possible by the advent of the El Paso & Southwestern railroad, affords an outlet for Phelps, Dodge & Co., operating at Tyrone, and has made mining at White Signal more attractive. Ore is now being hauled but a few miles to a siding. Ores contain gold, silver, and copper.

Silver City, November 24.

SOCORRO COUNTY

In the case of Thomas E. Waters, trustee, v. the Treasure Mining & Reduction Co. of Mogollon, Judge M. C. Mechem, at Socorro, granted a decree of foreclosure. The property involved is valued at $287,395, and includes the Confidence group of mines, mill, millsite, and water rights.——Cleaveland and Weatherhead, operators of the Sunburst and Deadwood mines, and the Deadwood custom mill at Mogollon, have closed down temporarily in order to make needed improvements in both mines and mill, and after installation of machinery is made will operate on a larger scale. They have not yet fully decided as to what the changes will be. Operators expect to be in the market at an early date for a 50-hp. internal-combustion hoist, cages, and also a machine-drill sharpener.

OREGON

JOSEPHINE COUNTY

Two mining deals were completed at Medford on December 2, whereby the Old Channel mine, on Galice creek, has been sold to H. K. Owens, C. L. Creelman, and John C. Eaton, of Seattle, for $65,000; and a 75% interest in the R. A. Rowley mine, on Drew creek, to DeWitt Van Ostrand, of Wisconsin, for $30,000. The former mine has been tied up by litigation for five years. It was owned by the Old Channel Hydraulic Mining Co., of Chicago. The Rowley is a copper mine, and has three short adits.

A 30-ton cyanide plant is in full operation at the Queen mine near Leland, in charge of W. A. Burr.

MALHEUR COUNTY

The discovery of a large deposit of potash salts is reported 30 miles south of Vale. Los Angeles people are said to be negotiating for six sections of the ground.

UTAH

JUAB COUNTY

One of the U. S. Bureau of Mines rescue cars is at Eureka until December 22, and instruction is to be given to miners of the Tintic district.

Ore shipments from Tintic in November amounted to 348 carloads, or about 17,400 tons, valued at $435,000.

SALT LAKE COUNTY

Sales on the Salt Lake City Stock Exchange for the year were 3,329,943 shares (December, estimated), valued at $683,817, against 6,390,804, worth $1,234,628 in 1913. January totaled 326,951, and October 133,145 shares. This Exchange did not close on account of the war.

SUMMIT COUNTY

The Snake Creek tunnel is in 10,152 ft., 388 ft. being driven in November. Water flowing from the entrance is 8.3 second feet. A new Bury air-compressor of 9000-cu. ft. capacity has been installed, and better progress is expected. The ground at present is a hard mineralized limestone.

WASHINGTON

FERRY COUNTY

The Western Union Mines Co., at Republic, has secured a lease and bond on the Insurgent 'V' fraction and Ireland mines for $125,000. This deal completes arrangements for the development of the entire Republic group by J. L. Harper and associates.

STEVENS COUNTY

The Hecla Mining Co., of Chewelah, controlled by J. C. Argall and Fred J. Foster, of Spokane, has purchased machinery worth $2000. The orebody is to be opened by a 200-ft. shaft.

CANADA

British Columbia

The Granby company's plant at Anyox treated 47,000 tons of ore in October, yielding 1,800,000 lb. of blister copper. The cost was 8c. per pound. Two furnaces were in blast. There was also recovered 790 oz. gold and 25,000 oz. silver, the total value of the return being $262,300. The smelter at Grand Forks is now in part operation.

Ontario

At Cobalt the Cobalt Reduction Co. has started constructing a cyanide plant, to treat slime produced in the mill. The latter is now handling 300 tons of ore per day.——The McKinley-Darragh company will pay $67,431, or 3%, on January 1. Total to date is $4,404,709, or 196%.——The Buffalo property is now being operated at full capacity, and 250 men are employed.

Prospecting by hydraulicking at the Nipissing was stopped in November, owing to the cold weather. A total of 95.6 acres was sluiced during the summer. In October the water uncovered five veins near Peterson lake, and drilling on three of these has shown that one is 2 in. wide, assaying 2000 oz. per ton. Three open-cuts produced 10,385 oz. The high and low-grade mills treated 6709 and 154 tons, respectively, yielding $189,029 net value.

Underground work was resumed at the Alexo nickel mine on November 23, after a suspension of 3½ months. The daily output is 40 tons of about 4 to 5% ore.

KOREA

The Oriental Consolidated company reports as follows for September: 240 stamps crushed 25,533 tons of ore, and the cyanide plants yielded $129,096. Operating charges were $74,209, and development, etc., $8217, leaving a net profit of $46,671. The East Candlestick 10-stamp and Kuk San Dong 40-stamp mill were hung up for 13 and 33 days, respectively, through shortage of ore.

The October output was $135,657 from 21,504 tons of ore. The Kuk San Dong mill resumed work on November 1, and it should run for two months. New concrete mortar blocks have been placed under 30 of the 40 stamps at the Tabowie mill. The rainfall was 7 in., making 90 in. for the year to date, an abnormally high quantity.

The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports the following results for November:

Stamps working	10
Time, days	28.5
Ore crushed, tons	6,241
Total recovery	$73,000
Operating expenses	26,060
Net earnings	17,000

PHILIPPINE ISLANDS

A report on the Mambulao Placer Co.'s property includes the following data: The total area is about 830 acres, situated in the valley of the Mambulao river, in the Bay of Mambulao, and on the river Binutas, in the north part of the province of Ambos Camarines, Luzon. One claim is covered with a dense mangrove forest, the wood called *bacauan* being useful for boilers. The alluvial deposit varies from 25 to 65 ft. deep, averaging 36 ft., the first 5 ft. being clay and soil, 15 to 50 ft. of black soil made up of clay and decomposed vegetation, then a layer of 1 to 10 ft. of sand and quartz gravel, with a little clay, on a bedrock of soft, decomposed gneiss. Of 500 acres tested, 300 have averaged 72 *centavos* per cubic yard. Coarse gold exists, and is easily amalgamated. An 8-ft. dredge is proposed, and Joaquin Casanovas is now in San Francisco to place an order for one. Good profits are expected from this property.

PERSONAL

E. P. Kennedy is in San Francisco.

Bradley Stoughton has gone to Chicago.

E. Gybbon Spilsbury has gone to Arizona.

C. H. Wray has returned to London from Nicaragua.

E. H. Nutter is at the Engles copper mine this week.

F. Lynwood Garrison has returned to New York City from Santo Domingo.

W. DeL. Benedict is expected in San Francisco by the 21st or 22nd of December.

J. Magazumi, a mining engineer of Japan, is visiting the mines of the Lake Superior copper district.

Information is wanted as to the present whereabouts of W. W. Alexander, who was interested in mines in Mexico some twenty years ago.

Cutler B. Whitwell has returned to Nevada City after an absence of three months while examining the Gold Bank mine at Forbestown, California.

J. F. Thoan, who has been at Hot Springs, Arkansas, for some weeks, has fully recovered his health and will leave for Salvador December 22.

H. W. Hardinge is in Arizona, where he went to attend the American Mining Congress and for a three weeks' tour of the mining camps of that state.

The Le Conte Geological Club met at the department of geology, Stanford University, on December 19. The program was: 'Stratigraphy of the Tesla, Pleasanton, and San Jose Quadrangles,' by E. B. Hall; and 'Oligocene in Contra Costa County,' by B. L. Clark.

C. B. Lakenan, general manager for the Nevada Consolidated company at Ely, Nevada, and Jules Labarthe, general manager of the Thompson smelter at Thompson, were appointed by the governor, T. L. Oddie, to represent the state of Nevada at a hearing on the public lands question before the State Department at Washington on December 17.

The John Fritz Medal for notable scientific or industrial achievement was conferred, on December 2, upon Professor John Edson Sweet, of Syracuse, for his achievements in machine design and for pioneer work in applying sound engineering principles to the construction and development of the high-speed steam-engine.

Obituary

Augustus Waterman, long connected with numerous Comstock companies as secretary, and father of Douglas Waterman, died December 1.

John Pym Neville, who died at Oakland, California, December 8, as the result, probably, of internal injuries received a year ago in an automobile accident, was at the time of his death, president of the Selby Smelting & Lead Co. He was an Englishman, born in 1851. He came to the United States when 21 years old, going to St. Louis, where he joined the staff of the Collier White Lead Co. From the presidency of that concern, he came to the Selby company nine years ago, and he has been active in its affairs since. He was a genial, likeable man who in the Bohemian, Athenium, and Claremont Country Clubs was a familiar and welcome figure.

Old Freibergers will hold the annual meeting at Hofbrau Haus, New York, on December 19. It has been suggested that the society have a meeting in San Francisco in 1915; and the Old Academy wants as many as possible to return to Freiberg in 1916 to celebrate the 150th anniversary.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, December 17.

Antimony	15 —15¾
Electrolytic copper	14 —14¼
Pig lead	4.05— 5.00
Quicksilver (flask)	$52.50
Spelter	6½— 6¾
Tin	34½—36
Zinc dust, 100-kg. zinc-lined cases	9

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, December 17.—Copper is firm at 12.70, lead quiet at 3.80, and spelter firm at 5.50c. per pound. Dividends declared by the Butte & Superior, Chino, Homestake, Nevada Consolidated, Tonopah Mining, and Utah Copper companies total $3,292,414. Unfilled orders of the U. S. Steel Corporation on November 30 totaled 3,324,592 tons, against 3,461,097 on October 31, 4,396,347 tons on November 30, 1913, and 7,852,883 on November 30, 1912. The iron market is quiet and unchanged.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
Dec. 10	49.87	Dec. 2	49.33
" 11	50.00	" 9	49.91
" 12	19.87	" 16	49.83

The market has been firm, but shows a tendency to weaken. Insurance rates to India have fallen 25% since the cruiser 'Emden' was destroyed. Prices recede quickly whenever the Indian support is withdrawn, yet the undertone seems better. The steamer 'Manchuria' took silver valued at $75,498, say 155,000 oz., from San Francisco to the Orient on December 12. No silver was shipped from the Nipissing mine in November, the product being stored; but 269 bars, weighing 312,234 oz., were sent to England last week. The Tonopah Belmont shipped 178,851 oz. last week also.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Date.		Average week ending	
Dec. 10	3.80	Nov. 4	3.50

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slighly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
Nov. 19	55.00	Dec. 3	55.00
" 25	55.00	" 10	52.50
		" 17	52.50

A review of the copper situation appears in the New York letter of this issue. Exports of copper from the United States in 28 days of November totaled 45,182,000 lb., valued at $4,959,000. October exports were 64,932,261 lb., worth $7,873,928. During the past two months the principal movements were as follows, in pounds:

Destination.	October.	November.
England	21,156,144	17,025,000
Italy	22,166,413	1,852,000
France	5,874,394	14,361,000
Norway	7,453,411	1,590,000
Sweden	5,342,340	6,119,000

Lake copper has been sold up to 13.12c. for January delivery.

It is computed that only nine of the principal American copper companies are paying dividends at present. These are the Anaconda, Calumet & Arizona, Chino, Old Dominion, Phelps, Dodge & Co., Quincy, Tennessee, Utah Copper, and Wolverine.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Date.		Average week ending	
Dec. 10	5.50	Nov. 4	4.90

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1913.	1914.		1913.	1914.
Jan.	50.45	37.85	July	40.70	31.60
Feb.	49.07	39.76	Aug.	41.75	50.20
Mch.	46.95	38.10	Sept.	42.45	33.10
Apr.	49.00	36.10	Oct.	40.61	30.40
May	49.10	33.29	Nov.	39.77	33.51
June	45.10	30.72	Dec.	37.57	....

Tin is steady at 34.35 to 35.45c., according to quantity. In London the metal is £149 5s. per ton for spot, and £148 for future.

BOOK REVIEWS

ROBERTS-AUSTEN, A RECORD OF HIS WORK, being a selection of the addresses and metallurgical papers together with an account of the researches of Sir W. C. Roberts-Austen. By Sidney W. Smith. P. x and 382. Ill., Index. Charles Griffin & Co., Ltd., London, 1914. For sale by the *Mining and Scientific Press*. Price $6.

In preparing this attractive volume Mr. Smith has put metallurgists under a debt of gratitude by giving them in accessible form not only many reports on special investigations of permanent importance and interest, but also some of the greatest masterpieces of metallurgical teaching, and thereby continuing and multiplying the influence of a very beautiful and inspiring life.

The outline of Roberts-Austen's life with which the work begins, and the record of his work at the Royal Mint and at the Royal School of Mines, should both interest and stimulate young metallurgists, indeed those occupied in a wide range of allied subjects; while his addresses and the reports on his investigations serve as admirable models to those who are called on to address their fellows, to write professional papers, or to report to their employers.

The abstract of the first five reports of the Alloys Research Committee should be of great convenience to metallographists, in enabling them to run down in these admirable documents any specified information which they seek.

The theories with which Roberts-Austen dealt may be superseded, as nearly all theories must be when, in the fullness of time, they have done their necessarily temporary duty of assembling the existing pertinent facts in a form convenient for assimilation and discussion. The data which he recorded may be replaced by still more accurate and fuller ones. But his methods of presentation will retain their value unlessened, because they are adapted to the unchanging human mind. And herein lies the great value and justification of the present volume, that it teaches us things of persistent value, how to think, to examine, to report, and to address.

Roberts-Austen was a very great teacher primarily because he had the teacher's true spirit, because he considered not his own mind, but the minds of those whom he addressed, looking not in but out. The reason why, on returning to London, we went first to the Mint rather than to the National Gallery or to Westminster Abbey, was that we met there one who welcomed us not for his own sake but for ours; who was truly glad to put his researches off till night in order that he might quicken us. You felt instinctively that you drew inspiration from his look and presence, and became better fitted for receiving whatever is uplifting and broadening in the world's metropolis.

As the work of the physician is not so much to direct as to be followed, not to give good advice but to heal; as it is the work of each of us to do not only what is right from our point of view but more particularly what is effective, what will accomplish the good aimed at; so it is the work of the teacher not so much to utter what is true as to cause his hearers to accept the truth. It was through no vanity or pedantry that Roberts-Austen's language was beautiful and his outlook and his presentation studiedly interesting. It was not so much that this beauty and this interest served to give him readers and hearers, as that it made them read and hear with interest and hence to their profit. The beauty and the interest feathered his shafts that, holding true to line, they might pierce. What profits it to speak truths so disagreeably that nobody will listen, or so obscurely that the busy world refuses to do the duty which the speaker shirks, of shaping those truths so that they may enter? The first duty of the writer or the speaker is to fit his words to the task which they have to do, of entering busy minds and lodging there. On taking up many of our professional papers one is almost tempted to say "I would rather this had been interesting and intelligible than accurate."

It would not be amiss if the secretary of each of our engineering societies should urge each new writer, at least among those young enough to be plastic, to read this book with care. Indeed one may ask whether these secretaries have any duty more important than to guide young writers into readableness, and to impress on them the transparent snobbishness and egoism of writing primarily with the aim of barely recording thought or observation rather than of putting thought and observation into assimilable form, which almost necessarily means simple and pleasant form.—H. M. H.

FOURTH ANNUAL REPORT OF THE DIRECTOR (Joseph A. Holmes) OF THE U. S. BUREAU OF MINES. P. 101, index. Washington, D. C., 1914. This report covers the fiscal year ended June 30, 1914. The personnel of the Bureau totaled 426 at the end of the period, of whom 118 were in the field. There were 19 bulletins, 30 technical papers, and 4 miners' circulars published on various subjects, also the text of 26 other works was edited. A total of 1,039,603 publications was distributed, against 835,556 in 1912-13, 507,536 in 1911-12, and 110,504 in 1910-11. Appropriations by Congress for the year totaled $662,294. A summary of the more important work done last year shows the thorough study of coal mine and other explosions, mine-rescue training (29,975 men taught since 1910), timber in coal mines, use of electricity, mine ventilation, smelter fume, utilization of low-grade minerals, carnotite ores, saving in cost of fuels used by the government, coal studies, and petroleum and natural gas.

RECENT PUBLICATIONS

OIL AND MINING BULLETIN. Official monthly organ of the Chamber of Mines and Oil, Los Angeles, California. Vol. 1, No. 1. P. 31. This was described in the *Press* of December 12.

University of California publications, Berkeley, 1914:

THE AGASANA-LIKE GASTROPODS OF THE CALIFORNIA TERTIARY, by Walter A. English. P. 14. Illustrated.

SKULL AND DENTITION OF THE MYLODONT SLOTHS OF RANCHO LA BREA. By Chester Stock. P. 16. Illustrated.

U. S. Geological Survey publications, Washington, D. C., 1914:

GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEVADA IN 1913. Mines report. By V. C. Heikes. P. 42. The total value was $37,097,710 from 5,367,211 tons of ore.

GOLD AND SILVER IN 1913. General report. By H. D. McCaskey. P. 41. The gold output of the United States was worth $88,884,000, and quantity of silver 66,801,500 oz. worth $40,348,100.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN IDAHO AND WASHINGTON IN 1913. Mines report. By C. N. Gerry. P. 47. The output in Idaho was $24,119,049 from 2,451,592 tons of ore; and Washington $1,053,135 from 115,685 tons.

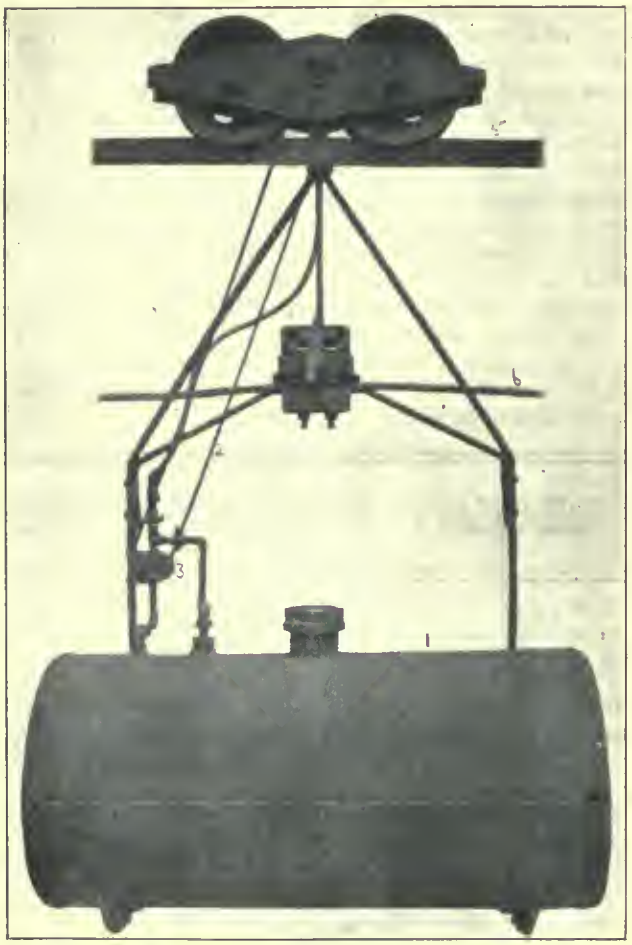
PRODUCTION OF NATURAL GAS IN 1913. Prepared under the supervision of David T. Day by B. Hill. P. 97. The yield of wells was 581,898,239,000 cu. ft., worth 15,10[illegible] per 1000 feet.

THE STONE INDUSTRY IN THE UNITED STATES IN 1913. By Ernest F. Burchard. P. 126. Maps, charts. The value of all classes of rock extracted was $83,732,995.

New Machines and Devices

Automatic Rope Lubricator

The accompanying halftone is that of an automatic lubricator as supplied by the Painter Tramway Co. of San Francisco. Lubricating the rope of an aerial tramway, if done by hand, is slow and tedious work, but a simple matter if the automatic lubricator is used. As shown in the illustration, the lubricator consists of a 50 to 60 gal. tank suspended in



AUTOMATIC OILING APPARATUS FOR AERIAL TRAMWAYS.

an iron frame and hung from a specially designed pulley from the track rope. As illustrated, the device consists of (1) tank, (2) chain drive for the oil pump, (3) small gear pump consisting of two gear wheels which acting on the principal of a rotary pump raise the oil from the tank to the rope, (4) flexible tubing used to conduct the oil from the tank to the track rope, (5) track rope, and (6) the power rope for moving the lubricator over the track rope.

Commercial Paragraphs

STEPHENS-ADAMSON MFG. CO., Aurora, Ill., in Bulletin No. 66, entitled 'The Labor Saver,' discusses several installations of conveying and storage methods as used at gravel deposits and quarries. The handling of large tonnages of material affords many interesting problems and those discussed are presented in detail with illustrations.

The DEISTER MACHINE CO., Fort Wayne, Indiana, has been awarded the contract for the installation of all concentrating tables in the mill at the Inspiration Consolidated Copper Co. The order was for 112 double-deck tables which will be delivered with all possible haste, but the actual installation will not be completed for several months.

DAVIS INSTRUMENT MANUFACTURING CO., Baltimore, Maryland, has issued a number of bulletins devoted to the various products of this Company. Among these may be mentioned the 'Sighting Compass,' 'Simplified Mine U-Draft Water Gages,' 'Blasting Magneto,' and 'Pitot Tube and Manometer. These bulletins are single-page leaflets, illustrated and containing a short description of the instrument treated.

BUSCH-SULZER BROS.-DIESEL ENGINE CO. is to install two Diesel engines at the plant of the Needles Ice Co., Needles, Cal. The purchase of these engines was after a thorough investigation of various types of prime movers, and it is hoped to have the engines installed and running by early summer. There will be two engines, one 500-b-hp. driving a 125-ton Ball ammonia compressor and one 120-b-hp. which will be direct connected with an alternating current generator. The engines are four-cyle, four-cylinder type with enclosed crank case, having large doors to give the greatest possible accessibility. Water cooling is used on the cylinders, cylinder heads, exhaust valves, piping, and piston as well as in the cooler for the lubricating oil.

The B. F. GOODRICH CO., Akron, Ohio, has recently received a report from the general manager of the French and English auxiliaries of the Company, in which it is stated that practically the entire stock of tires at the French factory and at the Paris stores has been requisitioned by the government. The tires were left in the Company's hands, but could not be sold to the public, the army having the right to call for them at a moment's notice and pay for them according to a preestablished tariff. There is no interruption in the production of band tires for trucks, but practically all that the Company could produce were used by the army. Recently the Company has been able to resume the manufacture of pneumatic tires on a small scale and also to offer some of the stock to the public. No difficulties have been experienced with regard to the supply of raw rubber and fabric.

CHICAGO PNEUMATIC TOOL CO., Chicago, Illinois, has issued a new publication entitled 'Small Power Driven Compressors,' which is Bulletin No. 34-S. These compressors have been designed to meet the demand for a small compressor which will be a simple, compact, substantially constructed machine requiring a minimum amount of attention. Quite a variety of small compressors are described in this bulletin, among these being the Junior No. 1 and No. 2, which has a 3-hp. engine with a hopper water-cooler on engine and a shaft pulley. This machine differs from other machines of this kind from the fact that the air piston is connected direct and in absolute line with the engine piston and the construction is such that the power is carried direct from the engine piston to the air compressor piston by means of a yoke, consequently the bearings do not receive any of the labor except as a machine which would be running empty. The machine is dust-proof and self oiling, which is one of the most essential points to be considered.

MINING ENGINEERS will be glad to know that a new and enlarged edition of 'Who's Who in Mining' is in preparation. Even incomplete as the early editions have been, the book has served a useful purpose, and it has the possibility of becoming extremely useful. The editor, Mr. George Safford, asks us to say that he will welcome from engineers in all lands, sketches of their lives that he may use in preparing the new volume. He may be addressed at 18 Eldon street, London, E. C., England.

PLANS for building a large zinc smelter at Swansea, Wales, to treat Australian concentrate, are reported to be temporarily in abeyance. The alternative plan of arranging for treatment in the United States through one of the existing zinc smelting companies or a new plant to be built by one of the larger metal companies, is also still under discussion. Great changes in trade movement cannot be made in one day and, for example, there is a question whether ore contracts with the German smelters have been terminated by the war or merely suspended. Profound changes in zinc smelting seem certain to result from the present war, but just what the changes will be cannot yet be stated with certainty.

CHILEAN nitrate producers are in a critical position, as is shown by the exports to Europe in October. Shipments to the Continent were less than 49,000 tons, compared with over 260,000 tons in the same month of 1913. Exports to the United States totaled 13,000 tons and 46,340 tons, respectively. On November 1, the estimated loadings for the United States amounted to 8240 tons, as against 5460 tons, but those destined for Europe were estimated at only 88,030 tons, as against 163,810 tons last year. The producers are making efforts to find a larger market in the United States. One difficulty is that the natural field for expansion is in the fertilizer trade, and here Americans are handicapped for the nonce by lack of potash.

DIRECT charges of graft are made in the suit recently instituted in the Supreme Court of New York county by Mr. Robert Holmes against the St. Joseph Lead Company and certain of the officers and directors. It is charged that an inferior grade of coal was substituted for the Carterville coal ordered and paid for by the Company, and that the purchasing agent profited thereby. The loss to the Company is estimated at $50,000 per year. We have previously referred to the difficulties in which the St. Joseph company has found itself despite the possession of large and valuable mines and the presence of most capable technical men on its staff. The situation emphasizes again the old truth that after all mining is a business and must be conducted with scrupulous regard to sound business principles, if it is to be successful.

COPPER stocks in Germany, according to the weekly report of the American Association of Commerce and Trade of Berlin are large and the Association quotes one of the foremost companies supplying war material, especially metal, as saying that should the war extend a great length of time, a sufficient supply of copper is on hand, and also that the company in question is in position to supply other industries. It has been reported, though how accurately is not known, that trolley wires were being torn down in Belgium to furnish copper for war purposes. In view of the German production and large stocks at the beginning of the war, it is not probable that this is true as yet, whatever may prove necessary in the future.

RAILWAY men are not the only ones pleased at the decision of the Interstate Commerce Commission allowing a five per cent increase in Eastern territory. It is only too true that the prosperity of the roads and of the country are so bound up together that one cannot be hurt without harming the other. The railroads must be allowed to earn enough to cover operating charges and suitable sums for maintenance and renewals. They must also earn enough to pay for expansion as needed or to pay interest and sinking funds on money borrowed for such work. All this is self-evident and generally admitted. The trouble has been that the general public has believed, and for that belief there has been entirely too much good basis, that operating charges have been excessive because of inefficient management, and fixed charges because of sums diverted from proper railway uses to the personal profit of insiders. By no means all railway companies can be properly so charged, but, as usual, innocent have had to suffer with the guilty; which is a crude rule society has evolved to make those who know an industry best police it. Management that is 100 per cent efficient cannot be expected in any very

large enterprise, and, speaking in general, we believe that the railways can offer in this particular much more to commend than to condemn. The other difficulty, that of excess capitalization, and heavy bonding, is a more serious one, and one not to be settled offhand. It is being studied and progress is being made, if only in the particular that property values are increasing up to the capitalization. In the meantime the railways must live and the systems must grow. A small increase in rates is not serious to the consumer of transportation and will greatly help the railways and their security holders. Therefore we welcome the decision. Most of all, however, we welcome it as an expression of what we feel to be profoundly true; that the public and public officials want to be fair to the railways and will be fair when met fairly and with a good case. This increase in rates has a moral effect. It stands, we think, in the same category as the five per cent decrease in wages accepted at one time by the coal miners in convention with the coal operators. It is an earnest of good intentions and a bond to keep the peace and work in harmony. As such, it is particularly welcome.

NICARAGUAN newspapers announced the cancellation of the so-called Deitrick Concession which blanketed a large part of eastern Nicaragua and in practice has served for several years to discourage mining development. In the judgment of a mixed commission which has been studying the situation the terms of the concession were never fulfilled and it has therefore been declared void, with compensation of $104,000 to its owners for the actual damage that this cancellation causes. The concession was granted originally to Mr. James Deitrick, but passed later to a group of Pittsburgh capitalists and politicians with whom Mr. Philander C. Knox was associated. It was popularly regarded as an incident to the 'dollar diplomacy' which he, as Secretary of State, promoted. It might have been the means of promoting development in a large and rich area, but actually it operated to hinder the opening of properties. The boundaries were not accurately known, only part of the transportation facilities to be furnished by the concessionaires ever materialized, and the hope of the United States & Nicaragua Company seems to have been to have others undertake developments from which it might collect a royalty. Engineers examining properties in the Pis Pis district under these conditions were unable to recommend them to their clients and the inflow of capital was blocked. Naturally there is rejoicing in that district now that the incubus is removed. At the same time it should be remembered that Nicaragua is a large and unsettled country: the building of roads, establishment of steamer lines, and other essentials to development will require much capital upon which immediate return is hardly to be anticipated; and unless the Nicaraguan government undertake these things in earnest the country is likely to remain largely undeveloped until some powerful financial group is given large privileges for a term of years.

THE END OF THE YEAR

The year closes with the world at war. At a time when by long established custom our thoughts should be those of peace, we can only read and think of the greatest conflict of modern times. Instead of Christmas carols and Christmas good wishes, more than half the world hears only the boom of guns, the shriek of shells, or, far from the field, the quiet words that tell of another loved one having died for his country. At a season when the World and his wife are accustomed to cease work and play at least one day with the 'kiddies,' thousands of children are starving to death. It is a terrible condition; one which we, here in peaceful America, can by no means visualize. We have troubles of our own, business has been poor with most of us, thousands are out of work, the Associated Charities have had to face increased demands with decreased revenues, and we are uncertain what the immediate future holds for us. With all that, by the good old method of contrast, we find ourselves well off, and out of the fullness of our gratitude we have been giving liberally to our less fortunate friends abroad. The work of the Belgian Relief Association, in which Americans have had such prominent and honorable part, is the one bright spot in the picture as the year draws to a close. The task is unthinkably large and the larger part remains to be done, but thousands of men, women, and children have already been saved from starvation. If that were all, it would in itself be a record of which humanity might well be proud. But it is not all. Perhaps the better part, the part that in the long years will count for most, has been the drawing out of the deep lying instinct to be helpful, that all mankind feels. The spirit of self-sacrifice is one of the most precious things in the world, and those who have gone without giving or receiving Christmas presents to help those they have never seen and will never see, have contributed to the making of a right *zeitgeist* more than they have given in dollars or in pounds. In turn, they have received more of value than any presents of other years. At a time when passions are roused, when smoldering racial hatreds are being fanned into flame by the incidents of the war, when men are ceasing to think in terms of the world, and organized murder is rampant, such an incident as the organization of international relief for the sufferers in Belgium is worth much. The war will end one of these days, and then will come the more difficult matter of readjusting international relationships so as to minimize the danger of recurrence of any such catastrophe. The work will be the easier and results a bit more certain because in the fight against suspicion, hatred, and self-interest this brilliant charge was made. Whether a boundary line be here or there, within limits, matters little as against the question whether we shall hate a man because he is a stranger and an alien. The Christmas spirit must struggle in this our year 1914 against many counter currents. Let each of us do what fate gives us the opportunity, to help it break through opposition.

TITANIUM

One of our subscribers who has discovered a deposit of rutile asks for information on the production and uses of titanium, and inquires what market there is for it. The situation in regard to titanium has materially changed during the past year, and its discussion is therefore of general interest. Titanium is one of the most abundant elements of the earth's crust, being present in most igneous rocks. Mr. F. W. Clarke has estimated that it forms 0.30 per cent of the earth's crust; in other words, it is one-half more abundant that carbon, ten times as abundant as barium, and fifteen times as abundant as nitrogen. It chiefly occurs as its oxide, TiO_2, and as a constituent of the mineral ilmenite, which may be roughly described as hematite in which part of the iron is replaced by titanium. Both of these minerals commonly occur in small amounts in igneous rocks, but large deposits, or concentrations, of rutile are not very abundant, as it does not seem to be easily taken into solution and re-deposited in rich concentrations. Nevertheless important deposits occur in Virginia, Georgia, New York, Maine, Arkansas, and other states, as well as in foreign countries. Ilmenite is quite commonly associated with magnetite, and until a few years ago it was generally supposed that immense deposits of titaniferous magnetite existed throughout the world, awaiting the discovery of a process by which they can be profitably smelted. An investigation made for the Bureau of Mines by Mr. J. F. Singewald disclosed the fact that the deposits are small, irregular, lean, and inaccessible except in a few instances, notably those at Sanford Hill, New York, and Iron Mountain, Wyoming, where large bodies of mixed ilmenite and magnetite occur free from gangue.

Early this year the McIntyre Iron Company leased a blast-furnace and began a series of experiments to determine the feasibility of smelting the ore from Sanford Hill, which contains approximately two-thirds ilmenite and one-third magnetite. By treatment with Wetherill separators a concentrate was obtained averaging about 55 per cent iron and 11½ per cent titanium. The blast-furnace was blown in on ordinary magnetite, and by gradual additions the charge was successively changed to $\frac{1}{16}$, $\frac{1}{8}$, $\frac{3}{16}$, $\frac{1}{4}$, and $\frac{5}{16}$ of titaniferous concentrate on the total charge. It was found that with the smaller amounts no change from normal working was noticeable except the formation of an unusually fluid slag. With the larger amounts it was found that the temperature of the slag was 150°F. higher than with ordinary ores, and the fluidity was much greater than normal. The titanium shows a tendency to replace silicon in the pig iron, and it was therefore hard to make a pig containing 2 per cent of silicon or over; malleable pig iron made from a charge $\frac{5}{16}$ titaniferous concentrate containing nearly ½ per cent titanium. It has been generally asserted that the presence of titanium in the smelting charge gives rise to a thick viscous slag and a high coke consumption; the experiments showed that the slag was unusually fluid and the coke consumption was normal. The pig iron produced during these experiments has been sold to consumers, but the records of the results attained in their use of it are not yet available.

All the rutile output of this country is produced by the American Rutile Company at Roseland, Virginia, which in 1912 produced 275 tons of rutile concentrate, containing 80 to 85 per cent TiO_2, and in 1913 produced 305 tons, containing 94 to 96 per cent TiO_2. The rutile occurs mixed with ilmenite, which is removed on magnetic separators, the material thus removed being well suited to the making of ferro-titanium. Much of the material produced by this Company is sold for export to Europe, but the quantity which can be sold is much less than the possible production, and the mill is only in operation during part of the year. It is evident, therefore, that the owners of deposits in the Western states would find it impossible to compete with the Virginia company, on account of the higher freight charges to the eastern seaboard, and it follows that the prospector has no incentive to search for rutile deposits.

Titanium is chiefly used for the production of ferro-titanium, which is made in this country by the Titanium Alloys Manufacturing Company, of Niagara Falls; the product containing about 15 per cent titanium and selling for 8½ to 12½ cents per pound. Some 1600 tons of this material was sold in 1911, chiefly for adding to bessemer steel for the production of rails, 153,000 tons of rails having been treated with titanium during that year. The titanium causes the steel to be more free from mechanically held slag, giving a superior quality of rail that sells for $1.50 to $2 more per ton than ordinary bessemer rails. Last year, however, less than 50,000 tons was so treated, the apparent reason being the growing use of open-hearth steel rails, which are also of superior quality and cost about $2 more than bessemer rails. The untreated open-hearth rails are of good enough quality so that the railroads are unwilling to pay for the additional cost of treatment. This decline in the use of ferro-titanium for treating rail steel, coupled with the success of the experiments in the direct production of titanium bearing pig iron, described above, seems to indicate that the demand for ferro-titanium for this purpose is likely to decline rather than to increase. Research work done by the staff of the manufacturing company indicates, however, that there will be a growing field for the use of titanium as an addition to copper and brass for the making of castings of those metals, it having been found excellent as a deoxidizer and therefore an aid in the making of sound castings.

Other uses of titanium are the making of 'magnetite' electrodes for arc lamps, the making of artificial teeth, the preparation of glaze for earthenware, the making of fused silica utensils, the preparation of titanium oxalate for use in dyeing leather and fabrics, and a few minor uses. The value of the total domestic output of rutile last year was estimated at $49,000 and it would therefore seem that the field of rutile production offers little attraction for the miner.

LOOKING FORWARD

This seems to be a day of proclamations and manifestos in Mexico when the various chiefs and *jefes* court the plaudits of the peon by statements which have proved in most cases empty of everything except words designed to be pleasing to the ear of the listener. These public expressions of plans and platforms have been both numerous and ridiculous as to application, but through them may be gleaned the real state of mind which has been responsible for the turmoil of the past four years, namely the struggle of the proletariat against the patrician, the peon against the great landlords.

Alberto Carrera Torres, general-in-chief of the 'Gustavo A. Madero' division of the Constitutionalist army, in a recent manifesto to the Mexican people declares the principles upon which the new *nacion* must be founded and what the Constitutionalist cause stands for. In reading over this wordy document one is impressed with the Utopian doctrines which he would expound for the uplift of the peon, and the bitterness of the class hatred which has been the cause of the trouble.

The purpose of the Constitutionalist cause, according to Torres, is "to secure happiness for our country by an era of peace and justice, and to guarantee to the *clases populares* an administration which will not oppress and exploit the peon class as has been the practice in the past. Under the old régimé there were no courts of justice established for the people, and as a result they have been the victims of a *rapacidad refinada* (refined robbery) by this *cientifico body*, who have looked upon the people as slaves." He thereupon proceeds to dispossess and depose by this manifesto all those connected with the old régimé, an act which has been repeated so often by Constitutional chiefs that it has become the standard procedure. He recognizes the authority as represented at the Aguascalientes convention as supreme and representing the purposes for which his army has fought. The laws of the country are recognized to be sadly deficient, and a reform is necessary whereby the lower classes of society will be received on a plane of equality with those of the upper class. It is emphatically stated that "The corrupt and rich class represented by Porfirio Diaz, Victoriano Huerta, and their followers has been protected by authority which was wrongfully set up, and under this protection have oppressed our brothers who form the supreme lower and middle class of society. It is necessary for our welfare that we break forever these chains which have wrongfully held us subjects of this *cientifico* class."

To meet the requirements essential to the welfare of the people, the debts which were contracted by the nation through the medium of the *cientifico* party and its successors—Huerta's administration—will in no manner be recognized. All bills owed to the *cientifico* party and representatives of this class are automatically canceled. In dealing with the officers of the federal army, it is ordained that no military titles conferred by the old régimé will be recognized by the new Constitutionalist government. A new military system is to be established whereby military instruction will be given throughout the Republic, this system to be in accord with the best principles of democracy and not for the establishment of a military despotism. Companies, batallions, and regiments will be organized in the various districts and given instruction in the use of arms and military discipline. Under the new *nacion* the Mexican people will have the full power of self government and will name and elect the officers in the various branches of the government.

The agrarian question, which has been the subject of such great diversity of opinion, is to be solved in a manner which will be entirely satisfactory to the lower classes. Property rights of those who have acquired property by means not approved by Constitutionalist *jefes* will in no way be respected, but confiscated and returned to the people. For the solution of this problem a committee has been appointed and given full power to act for the nation, which committee is to be known as the *Primera Junta Agraria*. This committee is to arrange details for the redistribution of confiscated lands and will be advised to distribute at once all *haciendas* which have fallen into revolutionary hands and that property formerly owned by Porfirio Diaz, Felix Diaz, Huerta, Mondragon, Blanquet, Reyes, Orozco, Iñigo Noriega, Creel, Terrazas, and others. This ground is to be subdivided into small holdings of 100,000 square metres (about 30 acres) each, and the title to one of these small farms is to be given to each of the families who have proper credentials and constitute the "*libre y soberano pueblo bajo y la clase media.*" In order to give an impetus to the agrarian movement, it is planned to drill wells and promote irrigation projects for the improvement of the lands to be distributed. The class to be particularly favored is designated in the manifesto as the *proletario*. Soldiers of the federal army who fought for the Huerta administration will not be barred from participation in this distribution, but will be apportioned land subject to their becoming and remaining loyal to the Constitutionalist cause.

Such is the material of which manifestos in Mexico are made, and the causes for the state of unrest. In the working out of the many plans proposed, the difficulties are many, and it is these details of the program which will cause no end of trouble. Manifestos, such as the Torres manifesto, have been numerous, and while the pervading sentiment is similar, there has yet to be developed an organization which will meet all the requirements of this many-sided people. Just how these manifestos will be translated into action and the people remolded into a commonwealth of one social status with unity of purpose and political creed is the task for a Titan. The Mexican reformer can see visions of such a Republic, but when reduced to the finite—*quien sabe*.

Persistence of Ore at the St. John del Rey

By T. A. RICKARD

*Two important gold mines are being operated in the state of Minas Geraes, in Brazil. Of these the Ouro Preto has no pretensions to profundity, but the Morro Velho mine of the St. John del Rey company has workings that have reached to 5350 ft. vertically,[1] or about 7600 ft. on the pitch (45° decreasing to 40° east) of the orebody. This mine was bought for £56,434 by the present Company in 1834. In 1867 a fire and the collapse of the open-cut workings necessitated the cessation of operations and the sinking of two shafts, 1122 and 1422 ft. deep, respectively; in 1874 work was resumed, but a second caving of the ground ensued in 1886, and the mine again became unproductive. Two new vertical shafts were sunk through the orebody to a depth of 2264 ft., this work being completed in 1892. Since then the mine has been developed by a series of internal shafts, each 1200 ft. deep, in steplike succession, the first being started 610 ft. east of the main shafts sunk from surface, and each of the succeeding ones 1420 ft. farther east, to be connected by a level parallel with the lode at a safe distance north in the country rock. This method is in itself an indication of the cautious policy of the manager, George Chalmers, who has never felt justified in looking sufficiently far ahead to incur the heavy expense of a more comprehensive system of development.

According to Orville A. Derby, of the Brazil Geological Survey, the lode lies[2] in calcareous schist, which is older than the Upper Silurian and possibly of even pre-Cambrian age. This schist, or calcareous phyllite, is, in part at least, a sheared representative of an older eruptive rock intercalated within an ancient sedimentary series that has been highly metamorphosed in consequence of orographic movements of considerable extent. Granite intrusions, in the form of bosses and dikes, exist in the vicinity of the mine. The ore is mainly a massive mixture of pyrrhotite, with arsenopyrite and common pyrite. Quartz is a subordinate ingredient. The typical composition of the ore is as follows: pyrrhotite 28.5%, arsenopyrite 5%, iron pyrite, 6.5%, quartz, 24%, carbonates of iron, lime, and magnesia together making 36%. Copper pyrite is usually present to a minor degree. According to Derby the lode occupies a fault plane dipping eastward at an angle of about 45°, the shape of the orebody being controlled by systems of jointing in the schist.

The annexed section (Fig. 1) of the mine is the one published in the Company's annual reports. It looks like the cross-section of a thick vein dipping at about 45°. This is not the case, as Mr. Derby's description has already indicated. The real character of the deposit is suggested by the plan (Fig. 2), in which I have shown the shape of the orebody at successive levels by difference of shading so that the superposition is made evident. The foliation of the schist is nearly vertical and the strike is 17°45′ east of north. Owing to the sinuous outline of the orebody and the progressive modification of shape downward, I am emboldened to suggest that faulting and jointing will not suffice to explain the structure of this deposit. The facts, to my mind, suggest a lenticular orebody within a folded schist. It is irregularly lenticular in horizontal section and incompletely funicular to vertical view. Apparently it lies in the vertical plane of the schist and pitches eastward in sympathy with an acute torsional fold, accompanied by slipping and shearing of the encasing rock. This interpretation is more favorable to the relative persistence of the orebody than one based on the structural conditions specified by Mr. Derby.

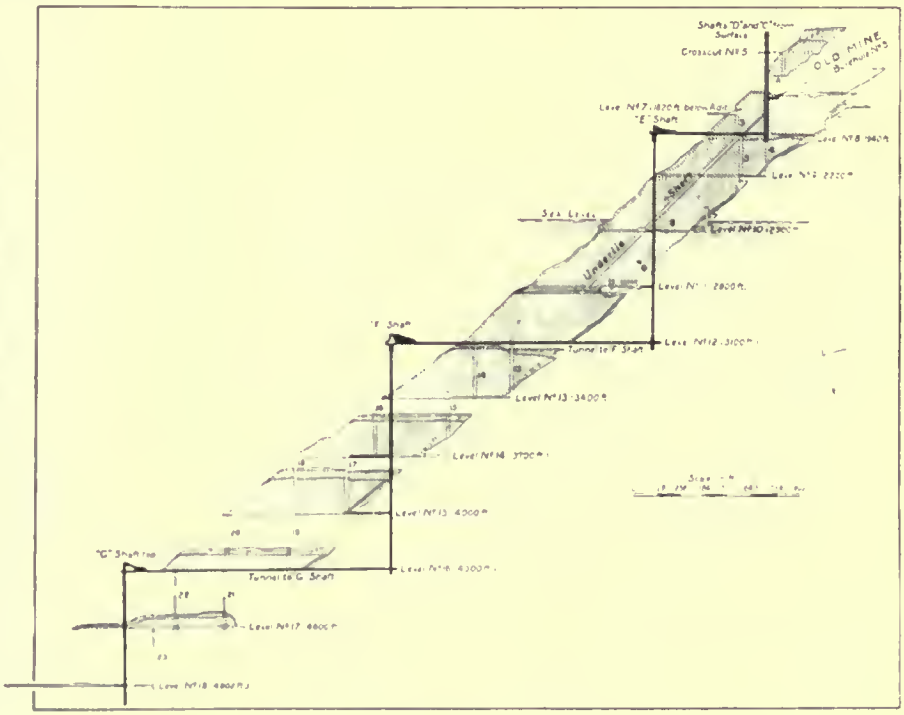

FIG. 1. LONGITUDINAL SECTIONS OF ST. JOHN DEL REY OREBODY.

*From 'Persistence of Ore in Depth,' a paper presented to the Inst. M. & M. London, November 19.

[1]In 1916 the shaft should reach Horizon No. 20 at 5826 ft. below the surface.

[2]As reported by him to the St. John del Rey company in 1901 and 1904.

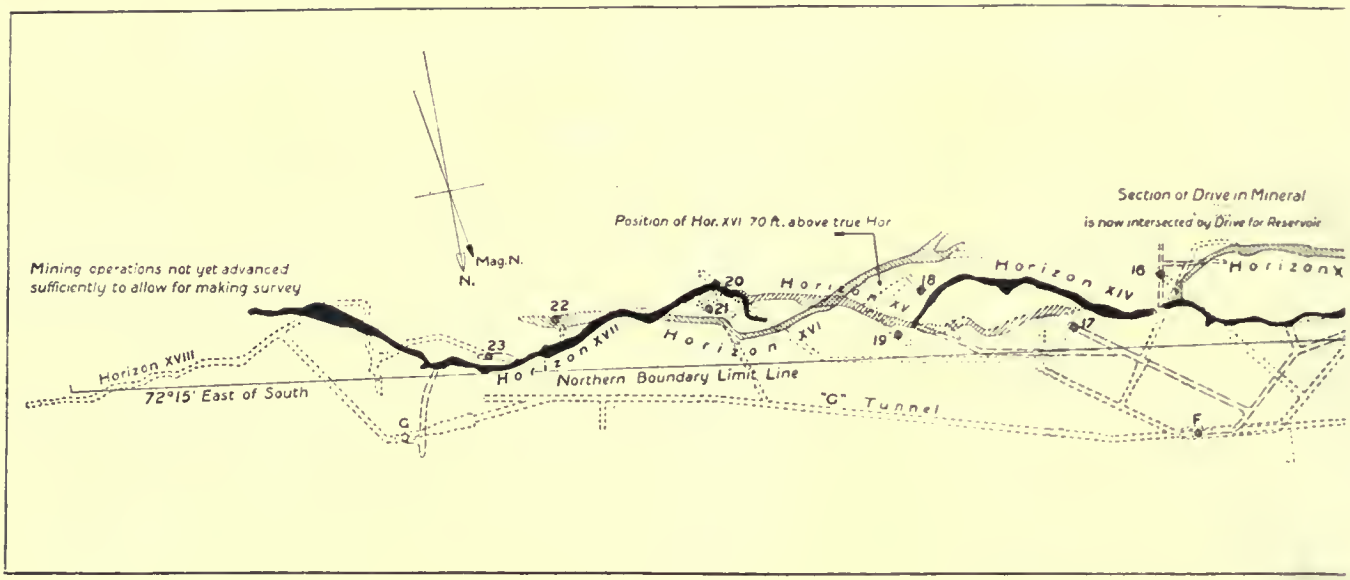

FIG. 2. PLAN OF ST. JOHN DEL REY

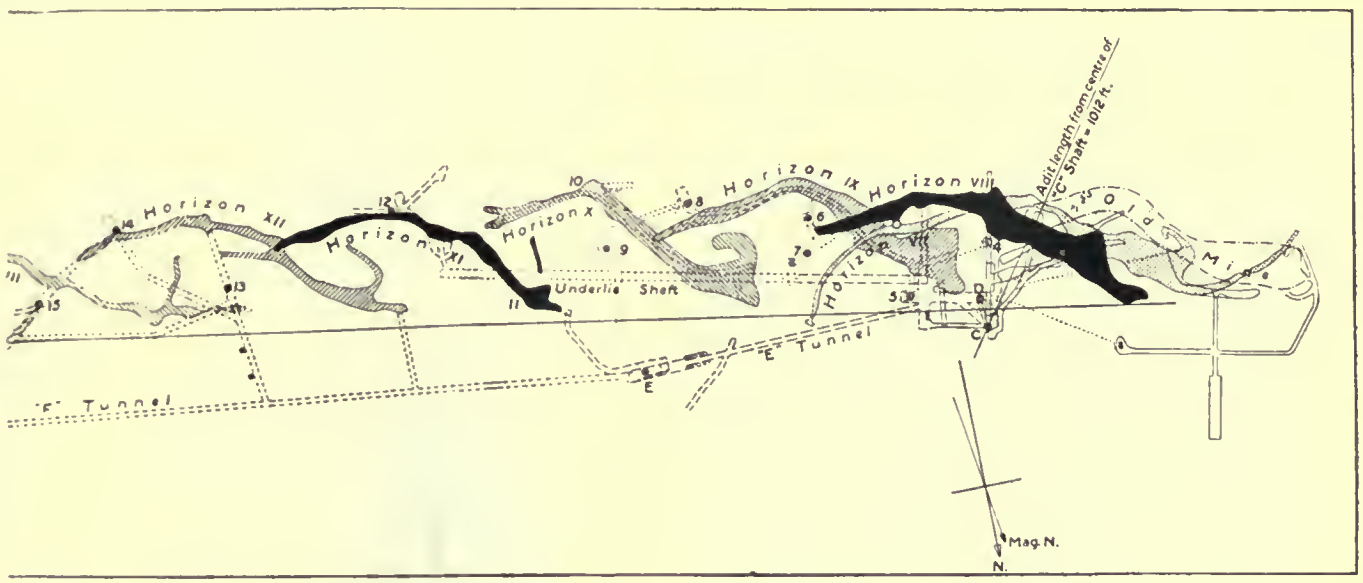
At the ninth level a 'horse' or inclusion of country splits the ore in its western and widest part. Indeed, down to the thirteenth the mine was in a parlous state, but on the fourteenth an enrichment of the eastern end became evident and has persisted ever since. Below the big open-cut the mine is dry. In 1901, however, on the eleventh horizon (3126 ft. below surface) some water was found; and it is said that this water contained "all the constituents of the lode." An analysis would be of great interest. In his report for June 1913, the manager, Mr. Chalmers, refers to the problem of persistence in depth. He mentions the careful study made by Mr. Derby, who expressed a favorable opinion at the time (in 1901) when the orebody showed one of those contractions to which it has been subject at intervals. Mr. Chalmers proceeds to state: "Since Mr. Derby gave his opinion we have explored the lode down many hundreds of feet, and find it has altered a little in shape, a very little in quantity, and improved in contents." He concludes that the increase of temperature, unless mitigated by improved ventilation, is the only obstacle to the deeper exploitation of the lode. The temperature increases 1°F. in 126 ft., so that the rock temperature at 6400 ft. will be 117°. This would be no serious obstacle, if the mine had vigorous ventilation through two main openings; as it is, the air comes down through a tortuous series of shafts, to ascend by an even more tortuous series of winzes. Ventilation is stimulated by a Sirocco fan of 150 hp. at the top of the C shaft. Another factor prejudicial to deeper mining is the system of hoisting, in steplike series up the various intermediate shafts and along their connecting levels. This must be costly. An incline-shaft, on the pitch of the orebody, was tried from the eighth to the eleventh horizon, that is, for a distance of 900 ft., but it was found to be too dangerous, as the schist 'blisters' and comes away in dangerous falls of ground. In depth the orebody has become longer (about 1000 ft.) and narrower (12 to 15 ft.) as compared with the nearly uniform length of 600 ft. and the width of 45 ft. exposed throughout the older upper workings.

From 1835 to 1892 the output of the mine was 2,958,593 tons, yielding £5,167,592, or nearly 35s. per ton: while in the period from 1892 to 1913 the output has been 2,715,933 tons, yielding £5,498,352 in gold, equivalent to 40s. per ton. In the first period 7.3% was rejected or sorted; in the second period only 5.7%. The total output was 5,674,526 tons mined or 5,313,028 tons milled for a yield of £10,665,944, which is equal to a yield of 39s.11d. per ton crushed. The mine was unprofitable for the first five years; between 1842 and 1867 the total dividends and bullion tax amounted to £896,500; from 1874 to 1886 the profit, as above specified, was £556,600; from the re-opening in 1892 to 1913 the profit was £730,266, so that the total dividends and tax payments amount to £2,183,366. During the last period a bond interest of £277,700 also has been paid. From the commencement about £1,000,000 has been raised for working capital.[3]

Reviewing the history of the mine according to the three productive periods, 1850-1865, 1875-1886, and 1900-1913, I find that the working cost (not the total cost) ranged from 17 to 23s. in the first period, from 26 to 30s. in the second, and from 25 to 31s. in the third. During these respective intervals the extraction in the mill has ranged between 52 and 80%, 70 and 75%, 71 and 93%. Dividing the history of the mine into two parts, before and after 1892, in accord with the statistics available concerning tonnage and yield, I find that the extraction averaged about 65% in the early period and 87% in the late one, improving to 92% during the last seven years. Now, if we make these allowances for loss in milling, we shall find that the 35s. per ton extracted from the shallower workings represented gold contents equivalent to nearly 54s. per ton as against the 40s. extraction and 46s. gold contents in the ore mined in the deeper workings. On the face of the evidence, allowing

[3]For these facts I am indebted to a historical account prepared by George Chalmers, the general manager in 1913.



OREBODY AT SUCCESSIVE LEVELS.

for difference in sorting, it seems to me that the lode cannot be said to have become either richer or poorer as it has been deepened, and that the St. John del Rey is an example of persistence to great depth. Yet I consider that the experience of other mines warrants us in commending the cautious policy of the management, which does not assume the continuity of the orebody for more than two or three hundred feet as measured at any time from the bottom level.

If the orebody follows a fold in the schist, it is obvious that similar folds along the strike of the schist may enclose other orebodies. Looking at the longitudinal section published in the reports, it is remarkable that so little exploratory work has been done outside the immediate limits of the known ore-bearing ground. Having regard to the unusual vertical extent of the workings, it would appear that lateral search for other orebodies is abundantly justified.

Origin of the Rocky Mountain Phosphate Deposits

By ELIOT BLACKWELDER

*Among the world's known deposits of lime phosphates, at least six genetic varieties have been clearly recognized:

Primary Pegmatitic (Norway), Guano (Redonda, Idaho), Marine Sediments (Tunis).

Secondary or Metamorphic—Surface residual concentrations (Querey), Phosphatized limestone and other rocks (Florida 'hard phosphate'), Detrital deposits (Florida 'river pebble').

The voluminous Permian(?) phosphate strata of Wyoming, Idaho, and adjacent states are marine sediments analogous to dolomite and limestone. Some points about their origin have already been established by Girty, Gale, or other observers. These are considered and to them are added other safe inferences as to the conditions of origin. The Rocky Mountain phosphatic beds apparently resemble those of Algeria-Tunis, Belgium, Wales, Sweden, and Tennessee (Devonian only); but are unlike those of Estremadura (Spain), southern France, Norway, Florida, the Carolinas, and the Peruvian islands. They belong, therefore, to the third class above noted. The foreign deposits most resembling those of the Rocky Mountains have been carefully studied, and the best interpretations of them, appropriately modified, seem to apply quite as well to our western beds. Omitting arguments, the chief points in the partial explanation thus far elaborated are the following: In the ocean, special conditions of currents, temperature, etc., not yet understood, may have induced the wholesale killing of animals over a large area and accumulation of the putrefying matter on the sea-floor in moderate and shallow depths. Anerobic decomposition produced ammoniacal solutions which dissolved the solid calcium phosphate present in bones, teeth, brachiopod shells and tissues. The putrefactive conditions also prevented the existence of sessile bottom organisms, and most calcareous shells descending from the surface were probably dissolved by the abundant carbonic acid arising from the decay. For physico-chemical reasons, already partly understood, the phosphatic materials were quickly redeposited in the form of hydrous calcium carbo-phosphates, locally filling, incrusting and replacing shells, teeth, bones, etc., but especially forming oölithoid granules of collophanite, and finally a phosphatic cement among all the particles. The granular texture is ascribed to physico-chemical conditions like those which result in oölithoid greenalite, limonite, aragonite, etc. After having been formed in quiet water, some of the granules were reached by bottom-scouring currents and incorporated in clastic deposits, and in some instances were even strewn over eroded rock surfaces and so become constituents of basal conglomerates.

*Abstract of a paper read before the Geological Society of America, Philadelphia, December 29-31.

New Plant at Mt. Morgan, Queensland

*Considerable alterations have been made at the Mt. Morgan company's plant during the past two years, and the general manager, B. Magnus, supplied the following data in November:

The old smelter has been entirely replaced by one consisting of three 54 by 336-in. blast-furnaces, fitted with 16-ft. forehearths and auxiliary forehearths. The height of charge possible is 25 ft. 7 in. Each furnace is provided with two outlets, one at each end, for discharge of matte and slag. All tapping blocks on the forehearths are of Australian chrome ore, in place of the usual cast-iron water-cooled blocks. Each furnace has a complete bustle pipe around it, and a main bustle pipe on both sides. The water system is in duplicate. The charge floor is airy and light, and devoid of fume. Ore and fluxes are conveyed in side-tipping cars, drawn by a 10-ton electric locomotive, to the floor, the furnaces being mechanically fed. Slag is carried in Dewhurst slag bowls, end-tippers holding 10 tons, and side-tippers 20 tons each. They are drawn by a steam locomotive. Two men handle about 1000 tons of slag per 24 hours. The flue system is as follows: a down-cast enters an independent dust chamber behind each furnace, connected by a catenary flue, which in turn joins with the main dust chamber on a hill. The latter chamber is 47 ft. wide, 31 ft. high, and 71 ft. long, with a stack 250 ft. high and 11 ft. diameter.

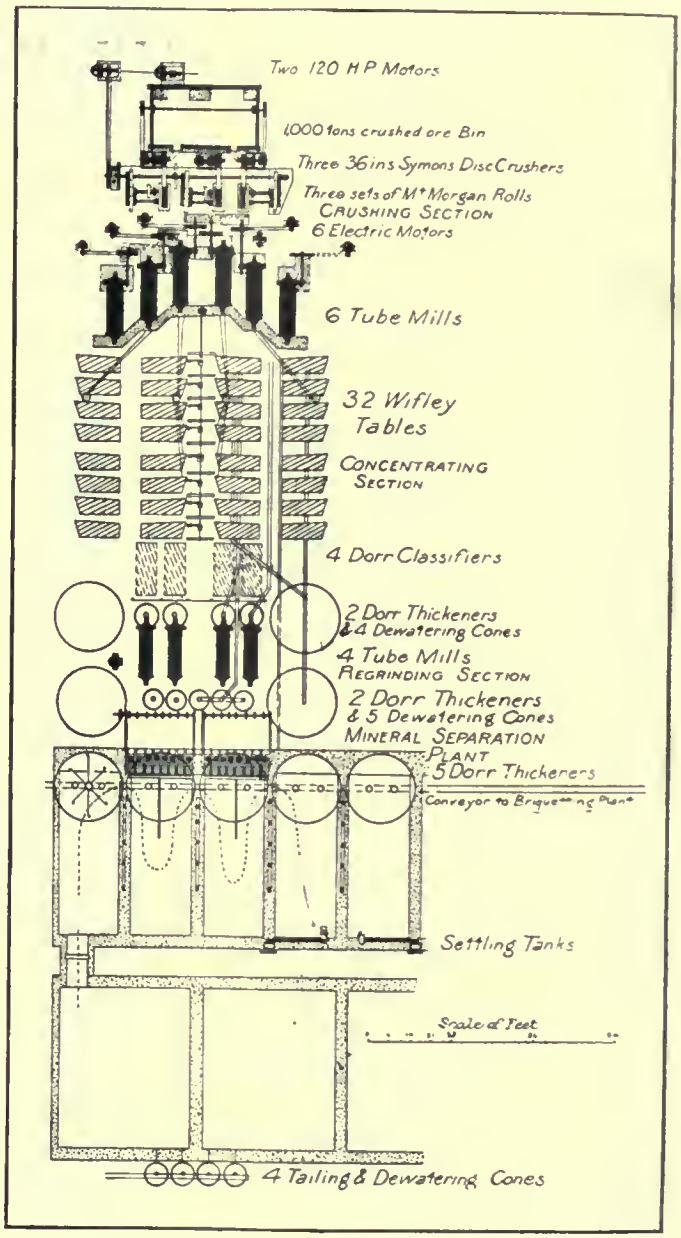
The New Concentrating Mill.

The new concentrating mill of 500-ton daily capacity is now in operation, treating the silicious ores of the mine, not economically treated by smelting. The accompanying cut explains the processes used. At the mine the ore is broken by gyratory crushers and delivered to the mill at 6-in. size. Two jaw-crushers reduce this to 2½ in. Suspended above a belt-conveyor which feeds these crushers are two high-power magnets which collect any iron and steel mixed with the ore, and which might damage the machines. The ore is then conveyed to a 1000-ton bin. Three Symons disc crushers crush to ¾ in., after which come three geared rolls and six Krupp tube-mills. The latter produce an 80-mesh product which passes over 32 Wilfley tables. The slime from these is thickened in Dorr machines, and the resulting pulp is treated by the Minerals Separation flotation process. All concentrates are drained, briquetted, and fed to the blast-furnaces. Basic converters are used.

The power plant for the mine and plants consists of the following: Six Babcock & Wilcox boilers of 20,000 lb. steam per hour capacity, and four smaller boilers; two 4000-ft. and one 2000-ft. Bellis and Morcan air-compressors; a Fraser & Chalmers mixed turbo-blower using exhaust steam from the compressors, compressing 10,000 ft. of air per minute to 14-lb. pressure; two Fraser & Chalmers blowers delivering 40,000 ft. of air per minute at 4 lb. pressure to the blast-furnaces; two Curtis turbo-generators of 1500-kw. capacity, and circulating pumps, condenser, and ice-making machine.

The smelter and power plant were erected on a slag dump, which is 70 ft. high in places.

The workshops are 480 ft. long and 60 ft. wide, and during construction of the new plant, $100,000 of work of all descriptions was turned out. About 200 men are employed in them.



FLOW-SHEET OF MT. MORGAN CONCENTRATING PLANT.

The output in the four weeks ended October 18 was as follows: The concentrating plant treated 6785 tons of ore, producing 1771 tons of concentrate containing 137 tons of copper and 1467 oz. gold; and the smelter handled 21,474 tons of Mt. Morgan ore, 5968 tons of Many Peaks pyrite, and 1629 tons of concentrate, producing 724 tons of copper and 9211 oz. gold. The value of this return was gold, $187,000, and copper, $190,000, a total of $377,000.

*Abstract from the Queensland *Government Mining Journal.*

Cyaniding Tailing in the Willow Creek District, Alaska

By J. T. TERRY, Jr.

The centre of the Willow Creek district, is about 35 miles northeast of Knik, a small town of approximately 200 population, situated on the northeast shore of Knik arm, a long narrow strip of water stretching northeasterly from the head of Cook's inlet. The country rock is a quartz diorite intrusive in a mica schist, and there are three sets or systems of veins. Those in the diorite strike almost at right angles to the schist-diorite contact. Those apparently parallel to the contact but in the diorite, and those in the schist strike at right angles to the contact. The latter are of the greater magnitude, but are barren or of low value so far as known.

The mines of proved value are on the first mentioned set of veins. The diorite is blocky and the fissures seem to traverse it for great lengths with small cross-fissures coming in from both hanging and foot-wall side. The quartz is usually accompanied by a gouge and vein filling and is from a white to bluish tint with reddish and green streaks due to arsenic and iron minerals. Many specimens show free gold, but the greater portion of the gold is finely divided and not visible till the ore is pulverized and panned. The veins in the diorite are from a seam to 12 ft. wide, averaging about three feet. The lodes that up to the present time have been profitably worked are near the summits of the divides between Craigie, a tributary of Willow, and Willow creek, and between Willow and Fishhook, a creek that flows southeast into the Little Susitna river which empties into Cooks inlet. The mountain ranges are steep and precipitous as a result of glacial erosion. The bottoms of the valleys and cañons are covered with detritus of boulders and gravel from terminal moraines.

The Gold Bullion mine where I erected and operated the first sand leaching cyanide plant in the territory, is the best equipped property in the district. It is situated near the top of the divide between Craigie and Willow creeks. The vein is of the blanket type and shows outcrops on both sides of the mountain. At several points where rich outcrops were opened, cuts were run or stopes driven to get out the ore, which stoped about two feet. The ore is transferred from the mine to the mill by two aerial jigback trams, the distance to the transfer or intermediate bin being 1300 ft., and from that to the mill 3800 ft. The drop between the mine and mill is approximately 1500 feet.

The ore is crushed in a five and a two stamp battery to 50 mesh, the pulp going over plates to a Wilfley table, thence to tailing ponds, and is subsequently cyanided. The cyanide plant consists of six leaching vats, sump, storage, and solution tanks, and has a daily capacity of 15 tons of tailing. The tanks, pipe, solution pump, etc. were furnished by the Pacific Tank & Pipe Co., and shipped from its Portland factory to Seattle, thence by steamer to Knik, and hauled in on double-end sleds

GOLD BULLION MINE AND CYANIDE PLANT.

drawn by horses shod with wooden snow shoes, during the winter of 1913. There is no road to the property. The equipment was transported over 2500 miles from the factory to the mine and arrived in perfect condition.

The plant was erected last May, the site at the time being buried under six feet of snow that had to be shoveled. Leaching operations began June 7, 1914. An extraction of 86.6% of the gold was attained from sand averaging $13.50 per ton. The cyanide consumption was 0.8 lb. sodium cyanide (129%), 2 lb. lime, and 0.57 lb. zinc shavings. The product assayed $34 per pound in gold, and about $4 per pound in silver. The product from the extractor boxes was roasted in a cast-iron pan without stirring, cooled, screened, sacked, and shipped to the Selby Smelting & Lead Co., San Francisco. The lime used was slacked by mixing one bucket of lime with three-fourths of a bucket of water, producing a dry powder which was screened, and a measured portion added to the cars.

The tailing, a 40 to 50-mesh sand fairly free from slime, was shoveled from the dam below the mill into cars holding two-thirds of a ton, dry weight, by two men, and run to the foot of a tramway 85 ft. long with a 30% grade, which then extends on a down grade of 2 in. in 16 ft. over the leaching vats. The cars are elevated by a water-wheel hoist. This power also drives the solution pump. The water is conveyed through 130 ft. of 8, 7, and 6-in. slip-joint pipe from the mill penstock, and applied under a 35-ft. head through a 2½-in. nozzle to a 36-in. wheel to which 24 iron elevator buckets are bolted. A loose belt and tightener operated by a lever is used as a control on the hoist. The water-wheel equipment was furnished by Meese & Gottfried Co., from their Seattle stock, and being light was easily transported; which is a very important factor in Alaska.

There is about 2000 tons of slime in the ponds which will be treated next summer by agitation and decantation. Agitation is to be accomplished by mechanical stirrers driven by water-power. The milling season in the Willow Creek district is from June 1 to October 1.

A Platinum-Gold Lode Deposit in Southern Nevada

By ADOLPH KNOPF

*The ore of the Boss gold mine in the Yellow Pine mining district, Nevada, has recently been shown to contain considerable platinum. The deposit occupies a vertical zone of shattering in dolomite of Carboniferous age. The gangue consists mainly of fine-grained quartz, but streaks of plumbojarosite are found carrying as high as 111 oz. gold, 99 oz. platinum, and 16 oz. palladium. Some 600 ft. from the mine is a small intrusion of granite porphyry, but no basic intrusives occur; in fact, none are known to occur in the whole district, which is the most productive lead and zinc district in Nevada.

*Abstract of a paper read before the Geological Society of America, Philadelphia, December 29-31.

Palladium: Its Characteristics, Uses, and Discovery in the Boss Mine

*Palladium is one of the rare metals belonging to the platinum group and occurring almost invariably associated with platinum or other metals of this group. The metal was discovered in 1803 by Wollaston, and named for the planetoid Pallas in honor of its discoverer, Olbers. The other members of the platinum group are platinum, iridium, osmium, rhodium, and ruthenium.

These metals collect in the lead button formed in the regular course of a fire assay for gold and silver. When this button is cupelled, the metal osmium is driven off, but all the other metals collect in the gold and silver button. If they are present to the extent of 2½% of the weight of the button, their presence is made apparent by a frosting and darkening of the button, while smaller proportions usually make themselves known in the course of the operation of parting.

Palladium is a ductile, malleable, white metal, which looks like platinum and is distinguished from the other metals of the platinum group by the ease with which it dissolves in nitric acid. It is strongly resistant to oxidation by atmospheric oxygen and moisture and to the effect of sulphur-bearing gases. For this reason it is employed for the inner mechanism of chronometers and watches, for the construction of fine balance beams, for the divided scales of delicate apparatus, and for surgical instruments. Like platinum, it is employed in the preparation of toning baths for use in photography. Another property of palladium which renders it valuable in some of the newer chemical processes is that of absorbing hydrogen. The price of palladium is practically the same as that of platinum, or more than twice that of gold, although on account of the somewhat lighter demand, it occasionally falls lower.

Most of the palladium comes from the placer mines of the Urals, Russia. Until recently the only mine in which palladium was found in this country was the Rambler mine, in Wyoming, where it is associated with platinum and copper. That it occurs elsewhere in minute quantities associated with copper ores is known from the fact that it is found in electrolytic copper.

A sample of ore from the Boss mine, Yellow Pine district, Clark county, Nevada, has just been analyzed by Walter S. Palmer in the state mining laboratory at the Mackay School of Mines with the following results: Palladium, 60.4 oz.; platinum, 12.28 oz.; gold, 38.92 oz.; and silver, 10.96 oz. per ton. A carload of 56,267 lb. from the mine, shipped to the American Smelting & Refining Co., gave the following returns: Palladium, 5.47 oz.; platinum, 1.1 oz.; gold, 8.752 oz.; silver, 9 oz.; copper, 0.97%; insoluble, 80.7%; sulphur, 0.5%; and iron, 6.7%. An assay made by Ledoux & Co., of New York, of a 340-lb. sample, gave the following results: Palladium, 16 oz.; platinum, 99.08 oz.; gold, 111 oz.; and iridium, a trace, per ton.

**Press Bulletin* 4, Mackay School of Mines, Nevada.

Examination of Placer Ground

By THOMAS A. GRAVES

The close agreement between the values as shown by prospecting and the actual returns from dredging under good conditions, together with the accuracy of estimates of the proportion of gold to be recovered under conditions not ideal, make dredging differ from other mining operations inasmuch as it becomes more of an investment and less a speculation. The greater the number of prospect holes, the nearer the two values approach each other. The personal equation of the engineer, however, is equally important. Aside from the amount of gold in gravel, the geological, economical, and climatic conditions must be given due consideration.

The geological conditions to be considered are: distribution, value, and nature of gold per cubic yard; depth of gravel to bedrock; size and frequency of boulders; hardness of bedrock and general contour of same; position of water-level referred to surface; and general nature of soil and gravel.

The economical conditions are: cost of land; cost of dredge suitable to use; cost of transportation; cost of supplies and repairs; cost and kind of power; cost of water for dredging; and wages and available skilled labor.

Climatic considerations are: whether arid or wet climate; whether cold or hot climate; and length of working season.

Effect of Various Conditions

Dredges designed to dig in exceedingly deep ground are more expensive to build and to operate; more power is consumed in operating digging ladder, and the stacker ladder has to be longer to prevent tailing from coming in too close to the dredge and thus prevent the spud from holding, which necessitates the use of inconvenient and more expensive head lines. Too shallow a gravel means loss of gold. Ground too hard causes additional expense for blasting and loss of much valuable ground. Gravel with a large amount of clay is injurious as clay forms a film around gold, making it not easily amalgamated. Ground containing large and numerous boulders prevents considerable ground from being dredged, and a close-connected bucket, which handles more gravel than open-connected, cannot be used. Frequently the richest gravel lies near bedrock or in crevices in it, and too hard or extremely uneven contour of bedrock makes it impossible to recover all this. If water level is too high it may prevent the digging ladder reaching the lowest depths, but frequently it supplies the dredge with water for working. Fifty miner's inches is sufficient water for dredge operation in clean gravel, but where large amounts of slime and mud are present, 100 in. or more may be needed. Whether or not the economical and climatic conditions are favorable is governed by the geological conditions.

Placing Prospecting Holes

There is no definite rule as to the number of holes required to be drilled to examine thoroughly a property. This can be ascertained as drilling progresses, but at the start the land may be divided into sections of from five to ten acres, depending upon the area to be examined, and a hole drilled in the centre of each. Before starting to drill or place holes, it should be noted whether bedrock projects to surface at any place and the probable course the gold took in deposition determined if possible. This precaution will often save many unnecessary holes being drilled, as one may start some distance from projecting bedrock and work out from either side and avoid shallow or valueless holes. On examining one property I observed that under the general course of a small surface stream, the bedrock was deepest and the gold most abundant and that from either side the holes to bedrock decreased both in depth and value. The elevation of each hole to be drilled is determined in reference to a common bench mark and from the depth of each hole the contour of the bedrock is determined, as is also the cross-section of ground.

Fig. 1 shows plan of test holes and Fig. 2 shows cross-section of ground and general contour of surface and bedrock for each row of holes drilled.

Method of Prospecting

My experience in prospecting placer ground has been with the Keystone No. 3 traction drill. This machine seems to keep its popularity mainly because of its being comparatively cheap to purchase and to operate, having few breakable parts, standing rough usage, and above all, giving satisfactory results. I have been in a position to know what the actual returns from dredging have been, and I was surprised to see in many cases how close the returns from prospecting and from dredging agree under favorable conditions, with sufficient number of holes drilled.

After the proposed distribution of the holes to be drilled is determined, the machine is moved to one of them, preferably near the centre of the channel and the following holes drilled on either side as conditions warrant. The machine, being placed, a hole is dug about two feet deep and shoe joint placed in it and soil filled around. The casing is then driven by driving blocks as far as soil will allow or until gravel is reached and then drilling is commenced. If no soil overcaps the gravel the drill is used at the beginning and casing settles as the drill goes down or it is driven with blocks.

Casing is kept a few inches in advance of the drill point to prevent any ground from running into the hole and to keep the area of hole the same as the shoe or $7\frac{1}{2}$ inches in diameter. As each length of casing is drilled or driven to head, the succeeding piece is screwed on and

the process continued. (In making connections care should be taken to clean carefully and oil the threads, graphite being preferred to prevent oil getting into hole.)

After driving the casing the drill stem is lowered into the hole and the difference between the mark on the stem and top of the easing represents the amount of core or material in the casing. Water is then poured in and drilling continued. Before all the core is drilled, the drill-stem is removed and the vacuum sand-pump is lowered into the hole and the material taken out and given to the panner. The machine man reports length and depth of casing and length of core, while the record

44	−2.5	−2.5	−2.5	43.6	. . .	..	0.50	Bedrock	Loose	.....

A, is the depth to which casing has been driven before drilling.

B, is the depth of the core after driving. (It is measured by the core left in the casing before driving, plus the amount of material forced into the pipe by driving.)

C, is the depth of the core after pumping.

D, is the difference in the depths of the bottom of the casing and core. (This enables the driller to know whether the casing is at all times below the point drilled. At no time should the drilling get below the casing except in particularly hard or coarse ground where the casing cannot be driven. The casing should be driven before pumping and a note taken as to whether any excess of material is taken out of the hole.)

E, is the depth of the hole after pumping.

F, is number of colors of No. 1, 2, and 3 classes of gold, No. 1 being largest and No. 3 gold the smallest size; 1^3 means 3 pieces of 1 mg. or under, 2^4 means 4 pieces of 2 mg. or under, 3^6 means 6 pieces of 3 mg. or under.

G, is the approximate weight of gold for each foot.

H, is the estimated volume of material from each foot after pumping, measured by the number of pans, each pan representing 0.01 cu. yd. for each foot drilled.

I and J, formation.

Remarks, include any other information considered important.

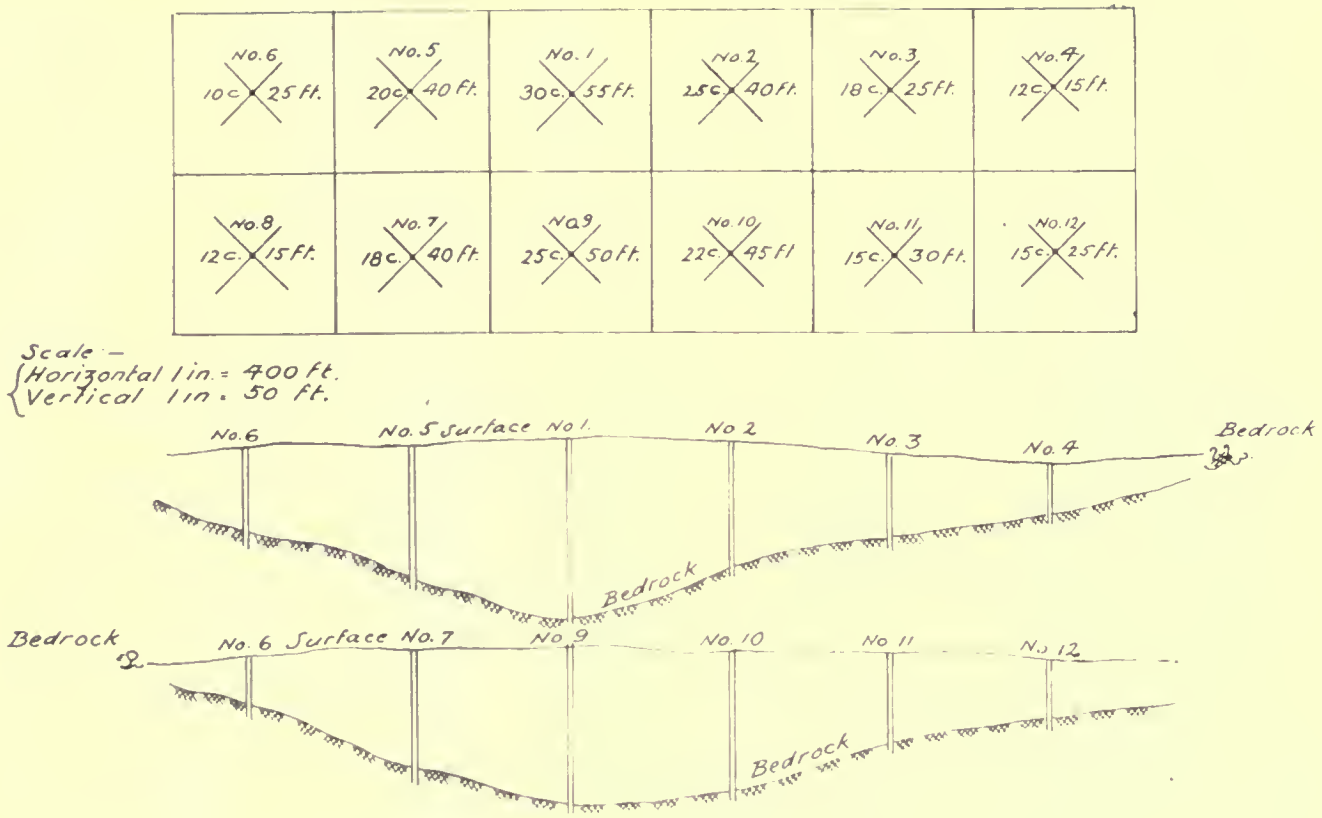

FIG. 1, PLAN, AND FIG. 2, CROSS-SECTION OF GROUND.

is kept by the panner. These operations are repeated with each successive foot that is drilled, and are carried on until lower limit of the pay-streak is reached, which is usually bedrock or a couple of feet below. When the desired depth of hole is reached, the pulling jars are used and the casing is removed from the hole and the machine is taken to the next location.

DETERMINING AMOUNT OF GOLD FROM HOLE

Each foot of material is pumped and panned and the gold estimated as to weight and number of colors. The apparatus needed by the panner in recovering the gold is a sluice box, rocker, tub, and pans.

The material is delivered from the sand pumps to sluice box and then transferred to the rocker. The concentrate is recovered from the rocker and then panned in a tub of clear water. The particles of gold found are preserved for assay when the hole is finished. If at any depth an unusual amount of gold is recovered, it is kept separate, as the gold may have come from a small seam that does not represent the true value of the surrounding material.

For assay the combined gold from each hole is amalgamated, then boiled first with diluted and then with concentrated nitric acid to dissolve the silver. The bead is then thoroughly washed, dried, annealed, and weighed. A small amount of alcohol added to the water wash prevents spattering of the gold.

LOG

The accuracy with which the value of ground may be estimated depends upon the completeness of the record of the field data and observations. Records should be entered by the panner and checked by the engineer in charge whenever possible. Measurements should be in feet and tenths. Table I shows a good practical log, and this, supplemented by that shown in Table II, make a complete record.

19. Total colors by weight, 200 mg.
20. Number of colors, 250.
21. Value of hole per cu. yd., 28c.
22. Remarks:

Calculating Volume

Great care should be exercised in ascertaining the amount of material taken from each hole. If ground has run into the hole while drilling, allowances should be made. The volume of material extracted from the surface to the bedrock or down as deep as pay goes, should be multiplied by area of shoe of 7.5 in. diam. and not area of casing. Radford's factor of 0.27 should be used if no ground has run into hole. Multiply depth in feet by 0.27 to get volume in cubic feet, and reduce to cubic yards by dividing by 27 or, divide the depth of hole by 100, which gives the same results.

Calculating Values

Each milligram of gold is worth approximately 0.06c. The value from this hole is 200 (milligrams) by 0.06c., equalling 12c. Volume of hole No. 1, 43 ft. deep, is by Radford's factor, equal to 0.43 cu. yd. Dividing the value of the gold in the hole by the volume in cubic yards of material gives the value per cubic yard, 28 cents.

Final Valuations of Ground

To obtain the average value of the ground, multiply the average yield of gold per cubic yard for each hole by its depth in feet. Add these various products and divide by sum of depths. The value of the ground equals the area multiplied by the average depth. The gross value of the ground equals the volume multiplied by the average value per cubic yard. The net value of the ground is equal to the difference between the gross value and the cost of land and dredge, cost of treatment, working capital, loss in tailing, and interest.

Cost of Drilling

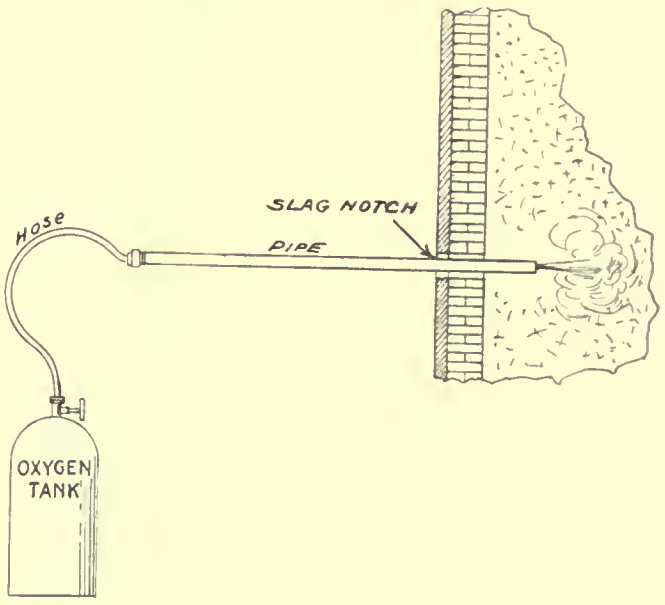
The cost of drilling varies from $1.25 to $3.50 per foot, depending upon the locality and the character of the ground. When drilling in countries where skilled labor is scarce it is better to pay men more and get those who can fill the various positions connected with the prospecting so that more accurate results may be obtained, and delays avoided. Approximate costs per day may be estimated as below:

Superintendency	$ 4.00 to $ 7.00
Machine man	3.50
Panner	3.00
Fireman	2.50
Teamster and team	4.00 to 5.00
Fuel	2.50 to 5.00
Miscellaneous	4.00
Repairs	2.50
Total	$26.00 to $32.50

Melting Out Slag Notches

An ingenious iron-oxygen torch for melting out frozen slag notches of blast-furnaces, and for similar work, is in use in a few places in this country, having been introduced here by David H. Browne from abroad.

When the slag notch of a furnace becomes frozen up the usual practice is to attack it with bars and sledges, and it not infrequently happens that the end of a bar is broken off in the notch, rendering the work even more



difficult. The hole may be quickly cleared by melting it out with this torch, which is constructed as follows. An iron pipe, so long that those handling it will not be burned by flying sparks, is attached by a short length of strong hose to an ordinary cylinder of compressed oxygen. The end of the pipe is then heated red hot in any convenient way, and the oxygen is then turned on. The red-hot iron at once takes fire and burns with an intense heat, giving off very brilliant sparks. It is at once introduced into the frozen slag notch and the fluxing action of the nascent FeO, combined with the intense heat, serves to penetrate the frozen mass with almost the ease and rapidity of a scoop penetrating cheese. The oxygen cylinder is the only part of the equipment necessary which is not commonly available at any smelting plant, and that may be obtained from an oxy-acetylene torch outfit, which is now usually not difficult to secure.

Treatment of Sulphide Ore at the Yuanmi Mine, Western Australia

*The sulphide plant at the Yuanmi mine started in September 1913. The ore, after drying, is crushed in a No. 8 Krupp ball-mill, and roasted in an Edwards duplex furnace with 60 rabbles. Cyanide solution is then added, and the roasted and oxidized ores are mixed, classified, and reground together in a tube-mill. The ore is finely ground but not slimed, about 14% being +150 mesh. The ground pulp then flows to mechanical thickeners, the resulting pulp being agitated. It then passes to a vacuum-filter of the fixed-leaf gravity-filling type.

Typical analyses of the ore treated are as follows:

Contents.	Sulphide. Per cent.	Oxidized. Per cent.
Insoluble	70.64	80.26
Fe	8.30	9.46
Sb	0.21	0.09
As	0.96	0.37
S	5.62	0.02
Co	trace	....
MgO	2.74	0.26
CaO	3.36	
Al_2O_3	2.02	5.09
Alkalies, etc.	6.15	4.15

The gold is very fine, but even in the oxidized ore is not always readily amenable to treatment by cyanide.

Oxidized ore from certain portions of the mine has the gold locked up in a hard flinty matrix, impermeable to cyanide solution. To obtain a good extraction from this particular class of ore, either very fine grinding or roasting is required, the latter being the process adopted here. Experiments have shown that extraction can thus be increased in some cases to from 56 to 96%, with roasting.

With sulphide ore, a thorough roasting is preferable, as the solution does not then foul. This does not appear to be indispensable, the addition of lead acetate and lime having marked corrective effects in cases of an imperfect roast.

Sulphocyanides are frequently present in the plant solution, and some trouble has been experienced with precipitation, due, probably, not so much to these impurities as to small quantities of arsenic and antimony. The precipitation troubles have been eliminated by substituting zinc-dust in place of shaving, a special type of extractor having been designed for this purpose.

Laboratory tests show that extraction is largely effected by fine grinding, sweet roasting, agitation, if not too thick a pulp, and the addition of lime and lead acetate.

The presence of unroasted sulphide ore in roasted or oxidized pulp lowers the possible extraction.

The antimony and arsenic are not totally removed by roasting, but, being oxidized, they do not prevent a good extraction.

Attempts to treat the unroasted sulphide ore by the Gitsham process proved unsuccessful. Other methods have also been tried, but so far without success.

Typical sulphur determinations are as follows:

Before roasting:		After roasting:	
Total sulphur. Per cent.	Sol. sulphur. Per cent.	Insol. sulphur. Per cent.	Total sulphur. Per cent.
3.64	0.54	0.02	0.56
4.07	0.65	0.27	0.92
4.53	0.75	0.21	0.96
3.80	0.69	0.20	0.89

During the 12 months ended August 31, 1914, 49,954 tons of mixed oxidized and sulphide ore was crushed and treated, the residue averaging $1.48 per ton, the extraction obtained being 83.5%. The tonnage handled was low, owing to the mill being closed down for a period of 77 days while the workmen were on strike.

The following table shows the proportions, etc., of oxidized and sulphide ore treated:

	Oxidized.	Sulphide.
Tons crushed and treated	30,111	19,843
Residue	$1.20	$1.90
Extraction, per cent	83.7	83.3

The annual report of the Yuanmi Gold Mines, Ltd., is reviewed on page 1013 of this issue.

*Notes prepared by Bewick, Moreing & Co., general managers.

Costs at the Yuanmi and Oroya Black Range Mines

These mines are in the East Murchison goldfield, Western Australia, and the following data are the report for the year ended June 30, 1914: The Yuanmi 20-stamp mill crushed 40,135 tons of oxide ore, and the Krupp ball-mill, 18,959 tons of sulphide ore. An Edwards furnace roasted the latter, while the vacuum-filter plant handled the joint pulp, the average recovery being 84.13%. The stamps averaged 9.93 tons per day. The Black Range 20 stamps averaged 8.75 tons, crushing a total of 54,460 tons. By amalgamation, leaching sand, and vacuum-filtering slime, a total extraction of 95.27% was made. Costs per ton were as under:

Items of cost.	Yuanmi.	Oroya Black Range.
Breaking ore	$1.38	$2.28
Filling stopes	0.20	0.09
Tramming and hoisting	0.87	1.20
Total mining	$2.45	$3.57
Rock-crusher	$0.10	$0.12
Ore transport	0.06	....
Milling	0.53	0.49
Vacuum-filter	0.70	0.48
Grinding sand	0.07	0.15
Precipitation and clean-up	0.46	0.10
Cyaniding by percolation	....	0.31
Disposal of residue	0.05	0.19
Drying	0.09	
Roasting	0.31	
Total treatment	$2.10	$1.84
Bullion charges	$0.11	$0.11
Re-treatment	0.05	0.10
Grand total, mine and mill.	$4.71	$5.62

DISCUSSION

Readers of the Mining and Scientific Press *are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.*

The Rand Banket

Reply by Mr. C. Baring Horwood to Discussion by H. Foster Bain*

Mr. Bain agrees with the importance I have attached to the retaining influence of shales, but reasons that as the gold occurs above and not below them, this forms an argument in favor of a detrital origin for the gold.

It may therefore be well to recall that I particularly called attention to the fact that the conglomerates have not such well defined or impervious walls as normal fissure veins, and that traces of gold can be found in all of the various series of conglomerates that occur in the Witwatersrand beds and in much of the intervening quartzites, demonstrating that the whole of these beds have been, to some extent, permeated by mineralizing solutions, but that the main circulation and mineralization had been confined to the well defined Main Reef series, that is, the lowest of the three series lying below the thick band of Kimberley slates and above the thick bank of Main Reef 'foot-wall' slates. The other two known as the Bird and Livingstone series are at a higher geological horizon and consist of small pebbles, and are relatively ill defined, and therefore, as one would expect, they usually contain only traces of gold. The flow of the mineralizers was thus practically confined to this well marked horizon, which is cut by dikes and large structural faults, by impervious beds both below and above, and this is what was to be expected if the gold is derived from deep-seated up-rising solutions.

Mr. Bain admits that I have advanced convincing proof that the so-called 'pebbles' of pyrite in the banket are metasomatic replacements, but he still has lingering doubts that this process took place long after the deposition of the Witwatersrand conglomerate, or that the pyrite and gold were introduced at a later period. I would therefore remind him that the mineralization extends into the numerous fractures that run through both pebbles and matrix of the conglomerate, and are parallel to the main fracturing and faulting of the district. Also, similar pyrite 'pebbles' of metasomatic origin occur in the well defined conglomerate beds of the Kimberley series and also in the banket beds of the Black Reef formation, and the gold in these beds is associated with pyrite, and also with these pyrite replacements, and frequently also with carbon. Further, the gold and mineralization generally of the bedded quartz deposits of the Dolomite formation, in the Pilgrim's Rest district of the Transvaal have been assigned by the Geological Survey to the neighboring intrusive igneous sheets and diabase dikes; and my own observations in this district confirmed this view. In like manner, I ascribe the mineralization of the Rand banket to the influence of the neighboring diabase dikes there, and I maintain (as de Launay[1] had previously suggested might be the case, if the theory that the gold was introduced after the deposition of the conglomerates be accepted) that there is no reason to assume more than one general period of mineralization to account for all the foregoing; and as de Launay remarked, this would merely mean that the banket is a special type of lode formation, and is a simple but particular type of those deposits (represented in South Africa by the various formations that carry gold-bearing pyrite) due to impregnation under pressure and in depth by mineralizers from an eruptive magma.

Before proceeding further, it may be instructive to recall the words of J. Malcolm Maclaren under the heading of 'Source of Gold' in his admirable work on the geological occurrence and geographical distribution of gold.[2] Maclaren states that "In the investigation of auriferous deposits no feature stands out in greater relief than the constant association of the primary goldfields with igneous rocks, and it therefore becomes necessary to examine the evidence available for the occurrence of gold as an original constituent of an igneous magma." He contends that the close connection between igneous rocks and auriferous regions may have been brought about in either, or both, of two ways. The gold may have been brought near the surface and within the reach of meteoric waters by inclusion within an ascending magma, or auriferous solutions may have been introduced by ascending waters that have a connection with igneous masses. In the absence of definite data, he assumes that the gold contents of many waters, especially those set in circulation by intrusive igneous rocks, as by the pre-Cambrian diabases, are derived from emanations from intrusive magmas, the emanations being finally dissolved in percolating waters, and by them carried into vein-fissures. He regards primary auriferous deposits as phenomena dependent on the intrusion of igneous magmas, and further as having an origin indissolubly bound up with that of metalliferous

*The delay in replying to this discussion has been due to illness.

[1]'Observations on the Rand Conglomerate,' by L. De Launay, *The Eng. & Min. Jour.*, 1903, p. 519 *et seq.*

[2]'Gold,' J. Malcolm Maclaren, p. 100 *et seq.*

sulphides or of the chemically related tellurides; and consequently, as he further remarks, work that throws light on the origin of pyrite is to be welcomed as assisting inquiry into the genetic relations of gold. Then under the heading of 'Transport of Gold' he states that gold in vein-waters may most reasonably be regarded as ionized and balanced either as auro-silicanion, as thio-auranion, or as telluro-auranion; that in the first case the deposition products are silica and free gold; in the second, free gold and sulphides, or possibly sulphides (including gold sulphide) alone, and in the third case, gold tellurides. He expresses the opinion that the first combination is the more probable in all those cases in which free gold is found studding clean quartz; and adds that even in many pyritous veins, deposition of pyrite, quartz, and gold has been contemporaneous. In such cases the gold would appear to have been held by both the first mentioned ions and to have been freed on deposition.

Now, it seems to me that these remarks have a considerable bearing on the Witwatersrand deposits; the latter constitute a vast goldfield occurring in a very ancient formation, and associated with igneous rocks. In this instance there is insufficient reason to ascribe the connection between the igneous rocks and the gold in the deposits of this region to inclusion of more ancient auriferous sediments that have been caught up and enveloped by the intruding magma. The oldest known sediments of the southern portion of the African continent are those comprising the Swaziland system, their geological horizon being between the Witwatersrand beds and the basement Granite, and it has always seemed to me that so far as one can judge from what remains of them at the present day, that it is improbable that they were sufficiently auriferous to account for the vast amount of gold in the Rand banket, either on the foregoing theory or on any placer theory; and the latter certainly does not explain why the gold should be confined in profitable quantity to only a few of the many well defined conglomerate beds. Some portion of the gold may possibly be explained by the first, or 'inclusion theory,' that Maclaren advances. The second alternative explanation that the gold was introduced by ascending waters that have a connection with igneous masses is, however, the view that I have advanced to account for the general mineralization, both auriferous and otherwise, of the Rand bankets; but I consider the rising solutions may have been largely in the gaseous condition.

I assume, in my discussion, that the mineral contents of the solutions were set in circulation by the agency of intrusive igneous rocks, such as are represented so largely throughout the mines in the form of diabase dikes, which are, as I have shown, doubtless genetically related to the Ventersdorp diabase, and that the mineralization of these solutions was derived from emanations from the diabase magma, and finally found a home between the walls of those pebble beds that presented even easier passages than ordinary normal fissures, and so became the channels of maximum circulation.

Tellurides do not figure in the Rand deposits. The latter are, however, certainly indissolubly bound up with metalliferous sulphides in the form of iron pyrite.

In my paper I showed by numerous analyses that the diabase dikes associated with the Rand banket contain both gold and pyrite, and also carbon, which latter also occurs in the banket.

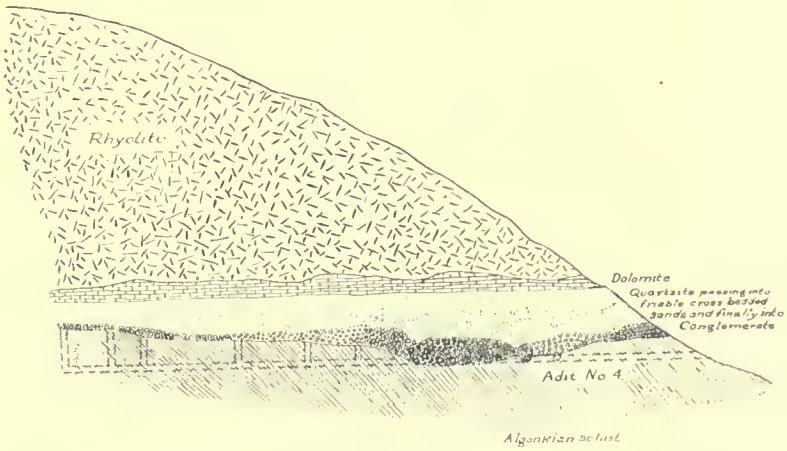
Then again, Maclaren's explanation of how the gold is carried in the mineralizers in an ionized condition and the consequent deposition products would account for the deposition of the gold, pyrite, and of the secondary silica in the banket. He states that in many pyritous veins the deposition of the pyrite, gold, and quartz has been contemporaneous, and I particularly pointed out that in the Rand bankets some of the gold and pyrite had been simultaneously precipitated.

Mr. Bain states that I give no figures as to the amount of iron present in the banket. The iron occurs, except in the oxidized zone, as iron pyrite, and in the first part of my paper I twice gave the amount of pyrite present as approximately 2 to 3% by weight of the auriferous banket. He thinks the sulphur of the pyrite may have been derived from sedimentary processes. This assumption was ably discussed in the criticisms on the paper read by Gregory in 1907 and was then shown to be highly improbable; I have already dealt with this theory in my reply to Gregory's discussion.

Mr. Bain says that the great supplies of gold have always come from placers. This may have been so in the days of more primitive gold mining. Apart from the Rand, which is the region under discussion, since the introduction of the cyanide process and the exploitation of the Western Australian goldfields and those of western North America, such a statement is no longer correct. Even if it were, it is not evidence in favor of the Rand banket representing an ancient placer. Advancing it in support of such a theory merely shows how difficult it seems to be (owing to the incident that between the walls of the Rand lodes ancient pebble beds are enclosed) for readers and observers to reason from essential field-relations, lode-characteristics, and facts, rather than from the supposition that auriferous pebble-beds can hardly be other than placer deposits.

Mr. Bain refers to those very interesting Cambrian gold-bearing conglomerates of the Black Hills of South Dakota described by J. D. Irving; he mentions them as an example of a fossil placer, apparently considering them somewhat analogous to the Rand banket. He says that Irving considered much of the gold was detrital, but that the pyrite represented action subsequent to deposition and was accompanied by enrichment of certain areas in the conglomerate. Bain then proceeds to argue that original sedimentary processes might explain such enrichment. Now, Irving's description of these Cambrian conglomerates of the Black Hills is very clear. They are at the base of the Cambrian series and lie on the Algonkian, from which they are separ-

ated by an unconformity. Above these is a bed of dolomite lying more or less horizontally, and above this again is a thick mass of rhyolite. Irving advances conclusive evidence to show that these conglomerates are of littoral origin and points out that as such they are exceptional in that they were not uniformly deposited along the shore, but were confined to the vicinity of a large gold-lode outcrop, and that the detrital material



CROSS-SECTION THROUGH THE HAWKEYE-PLUMA MINE, SOUTH DAKOTA.

from that lode was held in irregular depressions in the submarine surface in its vicinity. The pebble beds vary in thickness from a few inches to more than 30 ft. They are overlain by cross-bedded beach sands passing upward into quartzite. They are described as being often cemented by more or less indurated sandstone of a quartzitic nature. They are auriferous only in one locality, namely, in the vicinity of a great mineralized zone in the underlying Algonkian rocks, which Irving thinks was probably in the old Cambrian sea at the time of the deposition of the conglomerates. Upon this zone are the Homestake and other mines, and about it, occupying depressions in the old Algonkian surface, are the productive portions of the Cambrian banket.

The latter consists of rounded water-worn pebbles of quartz or Algonkian quartzite with an intersprinkling of schist fragments that seem to increase in abundance as the distance from the Homestake lode increases; it can be distinguished from the non-auriferous conglomerate by being cemented with iron oxide in the weathered, or pyrite in the unweathered, portions. Irving states that much of the gold is detrital, as proved by its water-worn condition, it is concentrated on the bedrock; and he states his opinion that this gold was derived from the erosion of lodes in the Algonkian rocks, and that enrichment of the lowermost layers of conglomerate has occurred through some of the gold having been dissolved later by ferric sulphate (resulting from the oxidation of the pyrite) and having been redeposited lower down, also that possibly some gold was introduced with the pyrite that once formed a large portion of the matrix of the pebbles. In the only productive areas then completely accessible it was found that along definite lines, in the centre of the stopes, there were values of from $5 to $12 per ton, while at distances of from 10 to 100 ft. away the values sink to between $1 and $2 per ton. Iron-stained fractures are found in the roofs of these stopes, and Irving suggests that the gold, which is distributed in low and fairly uniform value, is of detrital origin, and that the additional gold has been introduced with the pyrite along zones of fracture. In support of the latter part of this theory, he states that much of the gold does not yield to amalgamation, and that consequently the cyanide process is employed. He adds that the pyrite was introduced after the deposition of the conglomerate, as the mineralization extends into fractures in the quartz pebbles, and he thinks the pyrite is a replacement of the original cementing material, which elsewhere consists of quartzose sand.

He states that the rhyolite intrusions, which cut the conglomerates in places, are much mineralized with pyrite that is thought to be of post-intrusive origin, and that consequently this places the pyritic mineralization subsequent to the rhyolite intrusions.

I am very grateful to Mr. Bain for having called my attention to this occurrence, but the analogy that I draw between it and that of the Rand is different from his. If one refers to the accompanying sketch, which is a reproduction of one of Irving's sections through the Hawkeye-Pluma mine, it will be seen that there are several features of the occurrence that resemble those of the Rand. In each case the beds can be represented by geological columns that closely resemble each other. In the Dakota example they consist from below upward of ancient schists separated by a great unconformity from the overlying quartzite-shale-conglomerate series. Above the latter is dolomite, and this again by an outpouring of igneous rock. In the case of the Transvaal the base of the column again consists of ancient schists that are also separated by a great unconformity from the overlying quartzite-shale-conglomerate series. Above the latter is dolomite (with its thin basal Black Reef beds), and this is also capped by an outpouring of igneous rock. In the auriferous banket of the former example, the origin of the fairly uniformly distributed gold, averaging between $1 and $2 per ton, is ascribed by Irving to a neighboring lode in the older series of schists, and his evidence in favor of this is the adjacent locality of its occurrence, and its water-worn appearance. In my paper I admitted that some of the gold in the Rand banket may be of detrital origin derived from lodes in the ancient Swaziland schists. If so, since it shows no sign of being water-worn, it must have been subjected to those resolvent influences of which Gregory makes so much. Even if this be so, it is remarkable that in so vast a deposit none of it should have escaped this process sufficiently to still exhibit some indication of its original water-worn character. However, considering that the Witwatersrand conglomerates have been derived from the

denudation of the Old Granite and of the ancient schists of the Swaziland system, it is only reasonable to assume that they would have contained some detrital gold derived from these sources.

However, what I do maintain is that this great gold repository of the Rand had a much more plentiful source of supply of the precious metal than was afforded by the ancient underlying granite and schist: and that this reservoir was the barysphere.

Also, as in the Dakota example, much of the Rand gold does not yield to amalgamation, and the mineralization also extends into the fractures in the quartz pebbles. When dealing with the genesis of the carbon in the banket,[3] I pointed out that these fractures, running through pebbles and matrix, are parallel to the main structural faults of the district, demonstrating that the mineralization took place long after the deposition of the conglomerates, and later in my paper on 'The Rand Banket' I showed that much of the pyrite has metasomatically replaced not only the matrix but also the pebbles of the banket. I also demonstrated the close relationship between the pyrite and the gold, and that, to some extent, there had been simultaneous precipitation of the two, and that the evidence indicated the gold to have been introduced with the pyrite along zones of fracture communicating with the pebble beds. Irving lays stress on the fact that the rhyolite, which has broken through the conglomerate, is much mineralized with pyrite, and so thinks the pyritic mineralization was subsequent to the rhyolite intrusions. I showed that the diabase dikes of the Rand contain appreciable amounts of pyrite, gold, and carbon, all of which occur in association in the neighboring bankets, and that these dikes are genetically related to the Ventersdorp diabase, which is also appreciably mineralized with pyrite, and I consider the pyrite and gold mineralization of the bankets as one of the effects of the intrusion of these dikes.

Mr. Bain then refers to the gravels that are being dredged at various places along the Sierra foothills of California and says that the gold in them occurs distributed as on the Rand. Here I distinctly join issue with Mr. Bain. Can he instance a single example from among them showing not only regular alternations of relatively rich and poor zones in one and the same bed, but also showing similar alternations of rich and poor zones, as between itself and an underlying parallel bed, some 200 ft. beneath it, that is, rich opposite poor zones in the underlying bed and the reverse, like the examples illustrated by me in figures 25 and 26 of my paper? He speaks of the profitable beds as being miles in extent. So are the auriferous deposits of the Rand. What one wants to know, and what Mr. Bain is careful not to state, is not their extent along the strike but along the dip, or in other words, their width. On the Rand the profitable ground has been exploited to a distance measured on the dip corresponding to a vertical depth below the surface of from 4000 to 5000 ft., or some 6000 to 7000 ft. or more along the dip. Needless to say, the Californian placers do not average in width anything like this distance. Personally, I fail to see any real analogy between them and the Rand orebodies. Mr. Bain realizes that these Californian placers are delta deposits; he quite frankly admits that the diagrams given by me in illustration of the way the gold is distributed in the Rand banket make it quite clear that they bear no resemblance to river placers.

It seems to me that the Californian placers are largely responsible for the amount of mysticism that has arisen in regard to the genesis of the Rand gold. Many of the engineers who were first on the Rand in the early days of this great goldfield were well acquainted with the Californian placers, and owing to the strong superficial resemblance of the Rand deposits to the latter, they not unnaturally placed them both in the same category. Many who arrived later somewhat blindly accepted their dictum, as it is always easier to fall in with an already ventilated and plausible theory, rather than by careful observation to bring forward facts and arguments against it. There is, however, no longer any excuse for such procedure now that the mines have been so extensively worked and to such great depth, and for some 60 miles along the strike, and now that so much evidence is available that in those days was unknown.

I am glad Mr. Bain refers to the great contrast and unlikeness (brought out by Mr. Rickard in his discussion) between the Rand banket and the gold-bearing beach gravels of Nome. At Nome the profitable gold is limited to a narrow band, at most only about 100 ft. wide, corresponding to 100 ft. on the dip of the Rand banket.

The nearest analogy to the Rand deposits that Mr. Bain has seen are certain silicious deposits described by Irving as sandstones mineralized by solutions entering along transverse fissures and cracks. As a result of a brief visit to them, Bain considers the result is not at all the same as on the Rand, as he says the gold is localized and is more definitely related to fissures, which served as channels for the mineralizers, than is indicated by the Rand stope-plans published by me, and that 'pay-streaks' were formed rather than mineralized beds. Now, the stope-plans to which he refers are diagrams to show enrichment due to faulting, to illustrate the influence of faults on the distribution of the gold in the bankets. That we have mineralized beds rather than 'pay-streaks' in the case of the Rand is merely an incident due to the greater freedom offered to the circulation of the mineralizing solutions throughout the entire length of the beds, due to the porous nature of the conglomerates, which acted as pseudo-fissures. In ordinary fissures the original walls are relatively closer to each other, and the fissures as a whole do not permit such uniform and free circulation throughout their length, and such is only possible along certain parts, where consequently the maximum circulation and result-

[3] The Mode of Occurrence and Genesis of the Carbon in the Rand Banket, *loc. cit.*

ant maximum deposition occurs, such portions or channels often having been determined by dynamic forces that resulted in relative movement of the two walls, causing the intervening space to be diminished at certain points and increased at others, and so pay-streaks have been formed.

The Rand deposits must be viewed not with cramped vision but as a whole, when it will then be realized that the structural faults and the openings now occupied by the igneous matter of the numerous longitudinal dikes have furnished more than sufficient communications between the conglomerates and the deep-seated mineral reservoir of the earth's crust.

If the Rand gold is of subsequent origin to the deposition of the conglomerates and was introduced later as an incident of igneous activity, where, Mr. Bain asks, is any analogous deposit? This question gives me the opportunity of bringing forward an example to which Mr. Rickard has already directed attention, and that I consider is strikingly similar in essentials to the Rand deposits. The example to which I allude is that of the copper-bearing conglomerate of the Lake Superior district. Mr. Rickard describes this conglomerate as composed mainly of water-worn fragments of quartz-porphyry and allied rocks cemented by calcite, quartz, epidote, chlorite, prehnite, and copper, the pebbles of the first-named ranging in size from a pigeon's egg to that of a turkey. He states that in the deeper workings of the Franklin Junior mine the copper passes from the conglomerate into the underlying amygdaloidal diabase. Copper has been won on a large scale from the conglomerate in the Calumet & Hecla, Tamarack, Franklin, and Allouez mines. He describes the conglomerate in the Calumet & Hecla mine as from 10 to 25 ft. thick and dipping from 36 to 39° northwest, the profitable portion being in the form of an ore-shoot and pitching north. A bed of copper-bearing sandstone was exploited in the Nonesuch mine. Rickard points out, however, that in the majority of the mines the copper occurs in the associated amygdaloidal diabase, as for example in the Quincy, Atlantic, Baltic, and Wolverine mines. Also besides the copper in the beds of conglomerate and in the amygdaloidal rocks, copper-bearing veins occur that have been formed along lines of fracture, some of which have proved very productive. He aptly remarks that no American has attempted to establish an alluvial origin for the copper. I am tempted to wonder whether any of those who have, in the case of the Rand banket, suggested a detrital origin for the so-called 'pebbles' of such an easily oxidizable mineral as iron pyrite, would have dared to suggest such an explanation for the copper in what Rickard has termed the 'copper-banket' deposits of the Lake Superior region.

Rickard further points out that the associated basic lavas generally contain native copper, some of them being rich enough locally to invite mining operations; further that the copper banket has been formed by infiltration of solutions from which the metal in its native state has been generously deposited.

Native copper was first found in this region in the transverse fissures crossing the Keweenaw series.[4] Sulphides and arsenides of copper occur in fissure-veins in this region,[5] indicating that the source of the copper is deep-seated, and their close association with the diabase rocks suggests that their presence in the various deposits is due directly or indirectly, to the agency of these basic eruptives.

No 'fossil placer' bears such a close analogy, in those essential features that relate to genesis, as the 'copper banket' of the Lake Superior region does to the Rand gold-banket.

C. Baring Horwood.

London, November 3, 1914.

[Responding to Mr. Horwood's questions relative to the distribution of the gold in California placers now being dredged, we can assure him that the gold is distributed in a "direction corresponding to dip" fully as far as the instances he cites on the Rand. There is at Oroville a lower pay-streak than the one now being dredged. Being beyond the depth possible at present to work, it has been little studied, and it is impossible to say how the gold is distributed in it, whether according to the system he has illustrated from the Rand mines or some other. We are glad to say that arrangements have just been made for the U. S. Geological Survey and Bureau of Mines to join in a systematic study of placer deposits and mining methods. It is hoped that this will yield many significant results, and among others that it will throw light on this matter of the distribution of the gold at Oroville and elsewhere that the dredges are working.

Just a year ago we printed the last of Mr. Horwood's significant and interesting papers on the Rand. Today we close what has been an equally interesting and stimulating discussion which has run through the year and been participated in by many of the leading students of ore deposits. The papers and the discussion will now be reprinted in book form so as to make the whole permanently and conveniently available to students. In closing the discussion we wish to thank Mr. Horwood and those who have contributed to it, for the part they have taken in what we consider to be one of the most valuable series of papers that it has been our pleasure to print.—Editor.]

A cement plant with a capacity of 150,000 bbl. per year is about completed, at a cost of ₱600,000, at Binangonan, province of Laguna, Philippine Islands. A 5-mile aerial tramway will carry limestone to the plant. A pier has been built for shipment of cement to Manila. A barrel factory will use native timber. The works will be driven by electricity generated by steam, and 1000 men will be employed.

CONCENTRATES

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

GOLD PRODUCTION OF THE WORLD in 1913 totaled 411 tons, of which 274 tons came from the Transvaal.

RAINFALL at Johannesburg, Transvaal, averaged 31.5 in. for 26 years. Evaporation in 10 years averaged 73.59 inches.

WIRE ROPE of the locked coil construction is for heavy track cable service on aerial wire-rope tramways and cableways, and it is so named on account of the outer wires of the rope being of such shape as to permit them to lock within one another.

ACID MINE WATER in the Consolidated Gold Fields mines on the Rand is now neutralized by finely crushed carbonate of lime. This has resulted in less corrosion of pipes and pumps underground, and less burnt lime is needed in the mills and cyanide plants.

MANY IRON-ORE DEPOSITS on the Mesabi range contain as much as 20% moisture. This ore is not desirable for blast-furnaces, and gives trouble by freezing in cars during transport. Two drying plants are in operation in the Mesabi district during the shipping season. The ore passes through cylindrical rotary dryers heated by hot air from attached coal furnaces, a fan drawing off the water vapor from the ore, according to Edwin J. Collins. The Brunt plant contains two Ruggles-Coles dryers, 90 in. diameter and 55 ft. long, and two Economy dryers 84 in. diameter and 55 ft. long. These differ in heating and furnace arrangement from the Ruggles-Coles dryers. The Whitesides drying plant contains four Ruggles-Coles dryers, 108 in. diameter and 57 ft. long. In traveling through a 55-ft. machine, the ore passes 900 ft. of hot air. Moisture is not reduced below 7.5%, as fine particles are not suitable for blast-furnaces. The cost is 5.76c. per ton of ore for fuel, and about 20 to 30c. for all charges, while the value of the ore is increased by 35c. per ton.

AN INTERESTING PHENOMENON of the Ely, Nevada, district is the 'blout' or jasperoid, according to Alfred R. Whitman of the University of California. This is a compact granular silicious rock, generally of a yellowish brown color, forming bold outcrops along the copper belt. In a general way, it is arranged peripherally to the ore-porphyry; but the arrangement is irregular and ambiguous. A. C. Lawson has advanced the hypothesis that these deposits may be of the nature of an encasing shell about the porphyry due to contact action. But the better exposures due to mining operations of recent years have revealed evidence which does not support this view. The 'blout' in many cases caps the porphyry, but is nowhere found within it, while it is certain that a considerable thickness of the intrusive has been eroded away over the points where it is found. The occurrences of 'blout' are also notably conformable to the present topography. Had it originated from magmatic emanations, it must have incrusted the original periphery of the intrusion in addition to being distributed through the neighboring limestones and

SHOWING OCCURRENCE OF A 'BLOUT' AT ELY, NEVADA.

The irregular white line above the adit is the bottom of a mass of 'blout' five feet below the surface. The adit is in limestone dipping to the right.

shales as it is. These hard shells of silica, then, should have controlled the topography, preserving the underlying rock from weathering and erosion. But this is not the case. Many of the hills have jasperoid outcrops on the summits but they also have the same sort of outcrops in places here and there on the sides, even to the bottoms. In a few places the under sides of these outcrops have been exposed in prospect tunnels, as shown in the accompanying illustration; and in such cases are seen to extend irregularly down as fingers into the underlying limestones as complete replacements of it, as if they had resulted through the agency of slowly descending surface waters.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

BOSTON

Stock Exchanges Reopened with Good Trading.—Copper Producers' Association.—La Exposición Mining Co.—North Butte.—Southern Montana Railroad.—W. B. Thompson.

The Boston Stock Exchange opened on December 10 for limited trading, after having been closed since July 30. There were over 100 brokers on the floor, and a large and enthusiastic crowd of onlookers filled the balcony. When the gong rang it was apparent that there was a large number of buying orders on hand, and dealings started in a spirited manner. The strength of Boston's zinc issues, Butte & Superior and American Zinc, was the leading mining feature, both of them holding several points above the July 30 figure. Alaska Gold was several points higher, and Copper Range, Utah Copper, Inspiration, and North Butte were fairly strong. Many members of the Stock Exchange who do not usually visit the floor were present at the opening, and the feeling is quite optimistic as to the stock-market outlook. Boston traders are looking for the coppers to come back, and there is some feeling to the extent that the Lake issues, always favorites here, will lead the procession in the recovery. The position of the Lake stocks is very conservative and strong, and it is realized here that quite a number of the companies, both producers and development properties, are in sound condition through the restrictions enforced during the labor strike and the 10 months which have followed since the strike was settled. The passing of the dividend the second time by Calumet & Hecla is conservatively construed here, and the resumption of dividends by Quincy is well regarded. The strength of Copper Range since the Exchange reopened indicates renewal of interest in the Lake district. Lake, South Lake, North Lake, Mayflower, Old Colony, New Arcadian, New Baltic, and Oneco are prospect properties which have market promise. The Calumet & Hecla subsidiaries are in good financial shape, and a strong movement in them may be expected when the market turns.

The rumor that North Butte may acquire the East Butte mines and smelter is not given much credence in Boston, although it is recognized that such an eventuality is possible.—Freeman I. Davison, of Boston, will go to London in January to take up the campaign with financial interests there of placing $3,000,000 bonds of the Southern Montana Railroad, south of Butte.

It begins to look as if the monthly statements of the Copper Producers' Association are to be issued no more. The last one covered conditions as at July 1. There has been formidable opposition to the maintenance of a publicity bureau by the copper producers ever since the Copper Producers' Association was organized in 1909. The advocates of publicity having prevailed, the statements, once started, could not be discontinued for any logical reason until the war. However, it has been argued that the producers were financing a club to place in the hands of consumers, inasmuch as consumers, on that account, reduced the amounts of copper carried in their yards very heavily in comparison with amounts previous to the publication of monthly figures. L. C. Graton, a professor at Harvard, went to New York once a month to compile the figures as they have been gathered in by his office force there. Since July, producers to some extent have withheld the information they have been sending to the Association.

William B. Thompson, of New York, a member of the Stock Exchange house of Thompson, Towle & Co., and prominently identified with Inspiration, Mason Valley, and other mines, will retire from that firm at the end of December, as his position as a member of the Federal Reserve Board in New York forbids his sustaining such business connection. The business under Mr. Towle and some of his associates will be continued.

Application will be made to list the stock of the La Exposición Mining Co. on the Boston Curb at an early date. The moving spirit in this Company is Apollos Fuller, of Pasadena, California, who has been operating mines of this Company in Mexico and in the Turquoise district, Courtland, Cochise county, Arizona. The Company is capitalized for $2,500,000 and has an authorized convertible bond issue of $400,000. Calumet & Arizona and Phelps-Dodge interests have adjoining properties in the Turquoise district. The management has spent over $100,000 on the Arizona property, and the Mexican properties were producing and had paid dividends for some time prior to the war forcing them to suspend.

WASHINGTON, D. C.

Progress in Mining Legislation.—Bureau of Mines Publication.——Illinois Operators' Troubles.

Mining legislation in Washington proceeds at no faster gait than heretofore noted. While Congress is preparing to rush things, and will even sit through most of the holiday period, the skies will not become cleared for a sure outlook as to what will happen in legislation until after the new year. Meantime an interesting mining event is the forthcoming publication by the Bureau of Mines of a volume which shall be a compilation of all the mining laws of all the states together with those of the federal government. Such a compilation should be of great value. It will be tantamount to a sort of codification. It will certainly be handy to have around when the codification commission, which will come some time, begins to revise the national mining laws. The volume is not, however, going to be distributed free by the Bureau, it is announced.

Mining operators from Illinois have been in Washington to tell how sadly depressed the mining world is in many places. They have placed their claims and cases before the Secretary of the Interior, Franklin K. Lane, who can be helpful by the agencies of the department. The laws can be liberally enforced; stretching them tight might hurt.

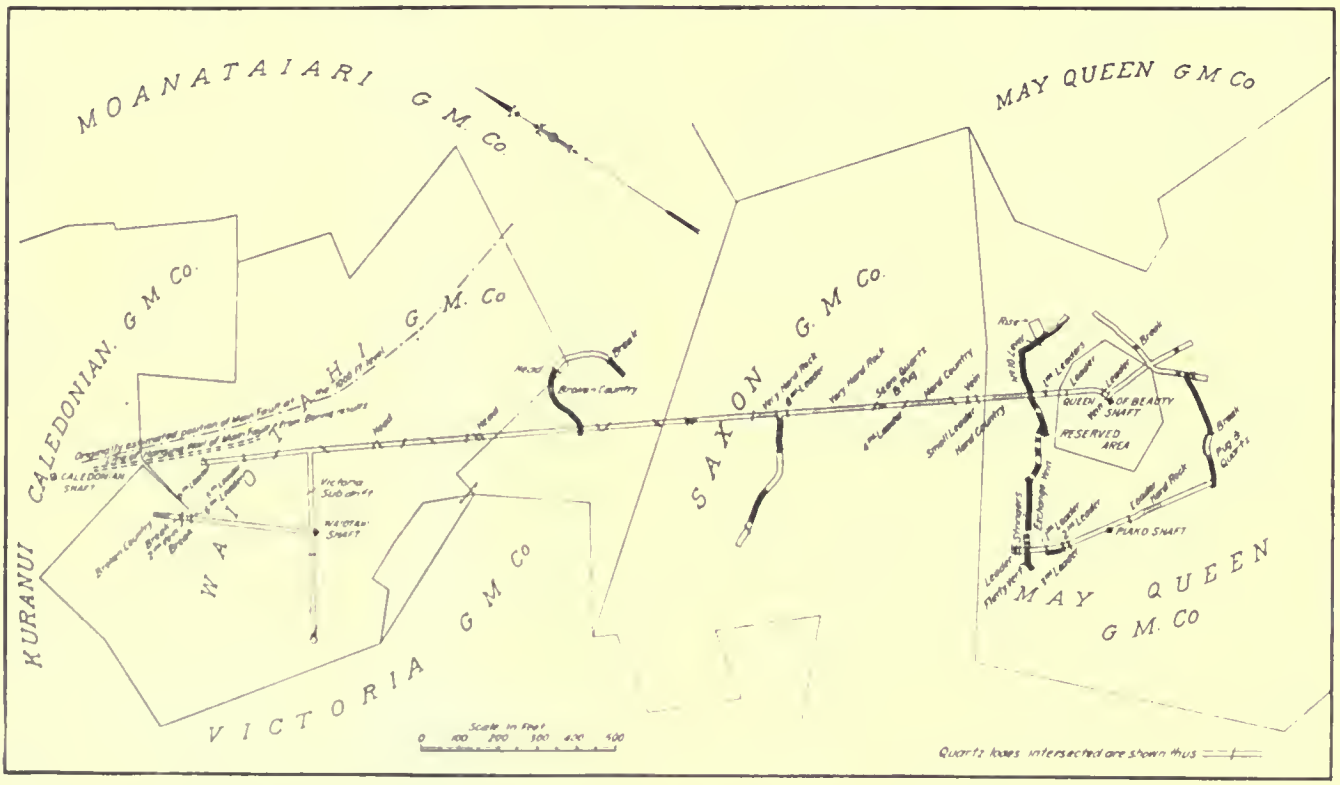
AUCKLAND, NEW ZEALAND

Résumé of the Past Year.—The Thames Deep Levels.—Waihi and Karangahake Districts.—Consolidated Group.—Oil Prospects.

The war in Europe, following on the strike toward the end of 1913, has naturally had a depressing effect not only on gold mining, but also the kauri-gum industry in New Zealand. Added to this there was a disastrous explosion at the Taupiri coal mines north of Auckland, which resulted in the death of 43 miners, and the stoppage of operations for some time. Even this did not end the troubles for the year just closing, as the sulphur company's works at White island, off the east

coast, were completely destroyed by a volcanic outburst and 10 or 11 men were killed. Thus 1914 has been an unlucky period for the mining industry of Auckland province. At the same time the important companies in the Waihi and Karangahake districts have carried on operations as usual, and yielded regular dividends to shareholders.

The most serious effect of the stringency of the money market as the outcome of the war, has been that shareholders in development properties have declined to pay assessments, and this has led to the stoppage of operations which means throwing a number of men out of work. The most regrettable thing was that this had the effect of compelling the Thames Drainage Board to stop pumping operations at the end of October. This resulted in the stoppage of work in the low-level crosscut, at 1000 ft., across the Thames district, to which no less Thames area is that all the five companies will amalgamate into one strong company, do away with the expense of a Thames Deep Level Board and Thames Drainage Board, and have all the operations carried out under the supervision of one competent mining superintendent. It is hopeless to do anything at the depth of 1000 ft. with a number of small companies attempting to carry on operations with penny assessments. The time has arrived when systematic development should be undertaken at the Thames to try to locate a second floor of auriferous country, in which might be found a downward continuation of the rich shoots of ore that yielded so generously near the surface in the early days of the district. It may be said that several mines here are independent of the pumping plant, and are at the other end of the field, but yields are small.



PLAN OF THE 1000-FT. LEVEL OF THE THAMES GOLDFIELD, NEW ZEALAND. THE CROSS-CUT, TO DRAIN AND PROSPECT THE AREA, IS ABOUT 2400-FT. LONG. THIS WORK IS DONE FROM THE QUEEN OF BEAUTY SHAFT, OTHER MINE WORKINGS BEING CONNECTED WITH THE CROSS-CUT. THE FUTURE OF THIS ONCE HIGHLY PRODUCTIVE FIELD DEPENDS ON RESULTS FROM THIS SCHEME.

than $106,000 has been spent during the past four years, and about a similar sum in keeping the pumps going. This suspension will thus mean the practical wasting of nearly $240,000, as once the water has been allowed to rise and fill the old workings, it will be a long time before any companies will be prepared to face the cost of unwatering the field again. The Waiotahi company had already sunk its shaft to 1000 ft. and connected with the cross-cut when the war started, but of course no development work could be undertaken.

On October 19 the government mine inspector gave formal notice that the deep-level cross-cut must be discontinued owing to the carbon dioxide gas being present in such large quantities as to make it a positive menace to the lives of the miners, if the ventilation plant should have an accident that caused it to stop for even five minutes. Under these circumstances there was no option but to stop work. Following this came an intimation from the Thames Drainage Board that it intended to cease pumping at the end of October owing to the interested companies declining to pay further contributions. This alone was enough to cause the stoppage of work on the deep levels, as the Drainage Board is a separate body that does the unwatering of the field. The only hope for the

The real mining work on the peninsula is in Ohinemuri county. The Waihi has produced a regular monthly output of gold and silver worth $120,000, paying quarterly dividends of 25c. per share. Better grade ore has been opened in the Waihi Grand Junction, and a dividend of 35c. per share was paid in November. The scheme to prospect the six miles between Waihi and the coast by a long adit and cross-cuts has fallen through owing to the war. The Waihi Reefs and Waihi Consolidated have been amalgamated and will sink to 1200 ft. to cut the Waihi lode system. At Karangahake, 9 miles away, the Talisman has yielded about $110,000 per month, the ore averaging about $24 per ton. The Crown mine, which adjoins the Talisman, and has produced $3,900,000 to date, had to suspend work owing to the lack of funds for development. Ohinemuri county has produced bullion worth $72,000,000, of which $28,000,000 has been paid in dividends.

The value of the gold mining industry to the Auckland province is shown by the fact that the total output of bullion from 1857 to the end of last year was $106,000,000, the total yield for the whole Dominion for the same period being $394,000,000.

In the Consolidated group of mines at Reefton, in the South

Island, important developments have taken place in the Progress section, which promise well for the future of that property. The Blackwater company had good returns throughout the year and paid regular dividends. According to recent advice, a vein has been cut in the mine at a depth of 1081 ft. assaying $35.50 per ton for a width of 36 inches.

The Ross Goldfields gravel mine, from which so much was expected when the fine new plant was in working order, and the Cassius lead was opened, has not so far fulfilled the hopes of the promoters, as the weekly returns are not equal to expenses. At the same time, there is still a hope for the company if vigorous development is undertaken, but at a time like the present people are not anxious to pay assessments, and this tends to limit exploration work in all mining ventures.

Development of the oil wells in the New Plymouth district seems to be slow business. In some places holes have been drilled to 3000 ft., and while barren as far as oil was concerned, gave valuable data for other operations. One of the companies appears to have spent all its capital on a refining plant, and was left without funds to prosecute boring operations. In some wells water has intruded in the oil measures with serious effects. No doubt in time all these difficulties will be overcome, and the day may arrive when New Zealand will be able to have a steady output of petroleum. That the oil exists in various places has been proved beyond doubt, but that it can be worked at a profit, still remains to be demonstrated.

PORCUPINE, ONTARIO

McKinley-Darragh Company Turns Down Jupiter Mine.—Teck-Hughes, Hollinger, Dome, Porcupine Crown, and McIntyre Mines.

The action of the directors of the McKinley-Darragh company, of Cobalt, in turning down the Jupiter property of Porcupine came as a surprise. The mine has been under option to the prospective purchasers since last spring, and all reports coming from the property and from the directors of the Company have encouraged the view that the option would be exercised. During the past few weeks the market for the shares had been strong, and the price gradually rose to 17c. A day or so before the decision of the directors was made public, large blocks of the stock were thrown on the market and the price broke to 10c. The option was for 51% of the stock and called for the expenditure of $30,000 on development, $50,000 for the retiring outstanding bonds, and providing an additional $40,000 for working capital. A couple of months ago the option was extended to December 17 to permit further development on the lower levels. This work is claimed to have given satisfactory results, sufficient to justify the property being taken over. It is understood that P. A. Robbins, of the Hollinger mine, who was formerly manager of the McKinley-Darragh, made an examination of the mine and advised that the option be exercised, while R. B. Watson, consulting engineer for the purchasers, was averse to taking up the property under the terms of the option. The directors of the McKinley-Darragh did make an alternative proposal which was not acceptable to the Jupiter company. Since the option was allowed to lapse, another offer has been made for the property by other people, but it has not been decided as yet whether to accept it or whether it would be more advisable to work the property for the Jupiter company.

Recent developments on the Teck-Hughes property in Kirkland Lake, which is under option to the Nipissing company of Cobalt, have not been as satisfactory as was anticipated. The ore-shoot on the 180-ft. level was much shorter than on the 80-ft. level, and the indications point to there being only a small tonnage of ore, on which the development charges will be high. The owners, however, agreed to remit part of the payment due, and the Nipissing decided to continue development, and is now sinking to reach a new level. The next payment on the property is due in March of next year.

Hollinger stock has been showing unexpected strength during the past few days, and this may presage the completion of the arrangements for the absorption of the Acme.

Minor changes are being made in the Dome mill with a view to increasing the tonnage to 28,000 tons per month. It is understood that total operating costs, including development, are approximately $2.85 per ton.

The Porcupine Crown has declared the regular quarterly dividend of 3%, payable January 2. While work below the 500-ft. level has not succeeded in opening any more ore, the southern extension of the orebody has been found beyond the fault, and development in that vicinity is satisfactory. The directors of the Crown Reserve company, of Cobalt, which holds the controlling interest in the Porcupine Crown, have intimated that it will again be necessary to cut the dividend of the Crown Reserve. This Company formerly paid 2% regular and a 3% bonus monthly, making 60% per annum. This was subsequently cut to 2%, and it is expected that the next rate will be 1% per month. If it were not for the revenue derived from Porcupine Crown, it is doubtful if even the latter could be paid very long from earnings.

During October the McIntyre mill treated 7510 tons averaging $8.84, and recovered $64,732. It is expected that the production for November will be in excess of October. A continuous decantation plant is being installed, and will shortly be in operation.

DEADWOOD, SOUTH DAKOTA

Homestake Affairs.—Anaconda Mine.—Tin Production.

With the declaration of an extra Christmas dividend of $1 per share, the Homestake gives substantial proof of having enjoyed a prosperous year. This payment will amount to $251,160, and with the regular monthly dividend of 65c. per share, will make a total of $414,414 paid to the stockholders in December, and a total for the year 1914 of $2,210,208. The property is now equipped with 1020 stamps, and during the year ended October 31, according to the report of the state mine inspector, 1,587,000 tons of ore was treated, yielding $6,046,000. Everything about the great property is working smoothly; there have been no changes of policy or methods, and while a number of changes have been made and are under contemplation, they are in the nature of permanent improvements and installations for the purpose of increasing efficiency and reducing operating costs. Along this line might be mentioned the central boiler plant, now under construction, from which will be operated a steam-driven electric generating station and a mammoth new hoisting equipment at the B. & M. shaft. The installation of electric pumps at Hanna, where water from Spearfish creek is pumped over a divide to a height of 382 ft. for supplying the mills, will effect a saving over the present steam-driven pumps. The poles and wires for the transmission of the power have been erected over the four miles from Englewood to Hanna, and the pumps are ordered. Next year, as soon as the ground is in shape for excavating, work will be started on a large and perfectly appointed hospital to cost upward of $25,000.

McNish & Mills are making an earnest endeavor to produce tin at Hill City, and are confident of success. They have already made a test run in a mill they have leased, and have had encouraging results. The mill is equipped with crusher and rolls, in which the ore is handled in a dry way. After crushing, it is sent to the trommels, where a large proportion of the mica is eliminated. This, by the way, can be marketed at $12 to $15 per ton. Following the second trom-

mel, where the water is added, the pulp is given a rough classification and fed to two Wilfleys and a slimer. The result is a clean separation on the Wilfleys; and, owing to the coarse crushing and thorough screening, a minimum of slime, which contains almost no cassiterite. No further milling will be done until spring, but in the meanwhile the plant will be equipped with some additional screening devices and a small furnace for producing metallic tin from the concentrate. These people have several properties under lease, but will probably be able to take care of a limited amount of custom ore. It is their intention to hand sort the ore and keep the grade at a minimum of 2% tin.

Removal of the hoist of the Anaconda company from the Elk Creek slope to the opposite side of the divide, on the Bare Butte Creek slope, has been completed, and sinking is under way. A two-compartment shaft is being put down and has reached a depth of 50 ft. Should the gold content of the ores at this point prove to be as good as in the old shaft, it will undoubtedly mean the construction of a large mill. Minneapolis capital is backing the enterprise.

LORDSBURG, NEW MEXICO

WORK OF THE 85 AND BONNIE MINING COMPANIES; NEW PLANT AND INCREASED PRODUCTION.

The 85 Mining Co. and the Bonnie Mining Co., both operating in this district, are making periodical shipments of copper, gold, and silver ore to Arizona and New Mexico smelters under general curtailment. The former's shipments for the past week have been retarded on account of bad roads between the mine and the loading point on the New Mexico & Arizona Railroad, but as soon as the weather permits, things will move along at a livelier rate than they have since An-

NEW POWER HOUSE OF THE 85 MINING CO., LORDSBURG, NEW MEXICO. PRIME MOVER CONSISTS OF A 450-HP. DIESEL ENGINE (LYONS.)

gust, when a curtailment went into effect. At the annual meeting of this Company held here last week, the following officers were re-elected: Arthur Warner, president; P. B. Yates, vice-president and treasurer; and C. H. Warner, secretary. W. F. Ritter will continue in the capacity of general manager, the position he has filled for the past few years. At the meeting, no decisions were made affecting the present operations of the 85 mine, owing to the unsettled condition of the copper market; however, it is stated by officials that an increase in production is contemplated. The Company decided to install an electric hoist at the mine, but the character was not settled upon. A night shift may be added to the working force of the 85 mine before long, and at which time connection will be made with the 85 power house for supplying the town of Lordsburg with electricity.

The Bonnie Mining Co. is working along steadily, and is installing new machinery. A steam hoist arrived at Lordsburg this week, and will be removed to the property as soon as road conditions permit.

NEW YORK

SAFETY AND SANITATION CONFERENCE.—BUTTE & DULUTH DEALS.—SHANNON COSTS.—BRADEN IMPROVEMENTS.—INSPIRATION BUYS THE KEYSTONE.

The feature of last week in New York was the Safety and Sanitation Conference, held under the auspices of the American Museum of Safety, in connection with the Second Exposition of Safety and Sanitation at the Grand Central Palace. Meetings were held during the week, dealing with the question of safety and sanitation throughout the whole country, and in every phase of work. Many of the papers were illustrated by moving picture films. So many papers were presented that it would be impossible to list them at length, but the ones most interesting to the mining profession were 'Safety in the Handling and Transportation of Explosives,' by W. B. Dunn, inspector of the Bureau of Explosives in New York. Various papers on fire prevention were given on Tuesday, December 15. Wednesday was industrial safety day, and the best papers were 'Safety in Underground Construction,' by Emil Diebitsch; 'Recent Progress of Safety in the Steel Industry,' by C. L. Close, head of the sanitation and welfare department of the U. S. Steel Corporation; 'How the United States Government is Helping to Decrease Accidents in Mines,' by H. M. Wilson, resident engineer of the Bureau of Mines Experiment Station at Pittsburgh. There were various other papers on standardization of safety devices and accident prevention. Thursday was devoted to transportation, and Friday to health and sanitation. Many good papers were presented, including one on conserving the health of workers at National Lead Co.'s plants, by Charles P. Tolman. Saturday was devoted to the welfare of employees, and a great variety of papers was presented. The sociological and safety work of the New Jersey Zinc Co. was described by Miss Florence Hughes, of the welfare department of that Company. The exposition was even larger and more interesting than last year, and the museum's work is showing a gratifying growth and increased influence in public life.

The Butte & Duluth seems to be rather elusive just now. A couple of weeks ago it was reported that it had been sold to Hayden, Stone & Co. It has since then developed that this is not a fact, but it is now reported that the Anaconda Copper Co. has taken an option on it at a price said to be near $2,000,000. The report is not confirmed by the Anaconda officials, and presumably the deal is not yet closed. There have been many rumors as to the future of the property.

The Braden mine has been doing well lately and the cost of copper at the mine last month is given as 7¼c. The recovery from mill operations is reported as being better than before, and presumably the smelter is working more smoothly, as Mr. Sorensen has been in charge for some time. H. C. Bellinger has been retained in a consulting capacity, and has been in Chile for the past few months.

The announcement that the Inspiration Consolidated Copper Co. will take over the Keystone, is an interesting conclusion to the suit which the Inspiration brought to secure permission to drive an adit through the Keystone ground to reach some of its own orebodies. The property of the Keystone lies between the Inspiration and Live Oak orebodies and consequently formed a bar to economic operation of the two as one property. The absorption is to be brought about by the exchange of 40,000 shares of Inspiration for 360,000 shares of Keystone. This property is under the management of the Lewisohn interests, though Ladenburg-Thalmann company are supposed to control the property. Development work has so far proved 2,500,000 tons of sulphide and 5,000,000 tons of oxide ore. This will form a substantial addition to the large tonnage of the Inspiration, though it is not enough to have promised much profit if the property had been operated as a single one.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

A preliminary report on mining in the territory, by Alfred H. Brooks, of the U. S. Geological Survey, will appear in the next issue of this journal.

Nome

Commercial business at Nome during the past season was as follows:

Vessel tonnage (arrivals and departures)	116,621
General merchandise received, tons	13,687
Fuel oil, tons	7,560
Coal, tons	2,087
Lumber, feet	1,482,359
Passengers arrived	1,584
Passengers departed	2,056
Placer tin sent to the United States, tons	108
Gold exported, customs and post-office, ounces	144,546
Value	$2,653,225

The Empire Tin Mining Co. is to develop its Bartel claims this winter, in charge of G. L. Blevins.——It has been reported that the large deposit of iron ore at Sinrock has been sold for $400,000.

ARIZONA

Cochise County

A considerable amount of general work is under way at the Copper Queen property at Bisbee. In the Czar and Holbrook sections of the mine, additional ore has been proved at 200, 300, and 400 ft. Shipments of the lead ore are going regularly to El Paso. In the Gardner mine at 700 and 800 ft., Lowell at 1100 and 1200 ft., and Sacramento at 1300 and 1500 ft., reserves of copper ore are larger than before. The new steel head-frame and hoist at the Czar are giving good service. The old boiler plant there is being remodeled, and a new trestle for disposal of waste is under construction. At the Holbrook the old sawmill and boilers are being dismantled. The central sawmill and drill-sharpening plant are at the Gardner mine. The experimental mill is testing concentration methods on the low-grade Sacramento ore. The precipitation plant at the Czar has been superseded by the new one at the Lowell. The new dispensary for the medical department is finished.

The report of the superintendent of the Shattuck Arizona, Arthur Houle, for the 24 days ended November 30, shows encouraging results, especially at 200 ft. The ore there contains silver, gold, and copper. A rise at 600 ft. is in 6% ore, while a rise at 900 ft. has opened good copper-gold-silver ore.

Gila County

The Old Dominion company is to do some churn-drilling between Globe and Miami, about two miles from the former town. The purpose of this work is to examine the formation in that part of the Company's property, according to the general manager, P. G. Beckett.

Graham County

The Shannon Copper Co.'s report for the third quarter of 1914 shows that 49,254 tons of Shannon and 11,459 tons of other Company ore yielded 2,964,764 lb. copper, 412 oz. gold, and 18,449 oz. silver against 56,085 tons, 11,379 tons, 3,118,156 lb., 420 oz., and 20,702 oz. the previous quarter. The cost of production was 11.396c. per lb., which covers all expenses. Including that from the railway, the total profit was $26,562. Owing to the war it was decided to shut the mine and smelter in September. The financial condition is good, as there was at December 7 the sum of $180,000 cash on hand, and 746,900 lb. of copper, which is worth $90,000. The Company also owns bonds in the Shannon-Arizona Railway Co. worth $383,000.

Greenlee County

The Arizona Copper Co. produced 2,690,240 lb. of copper in November.

Mohave County

Five feet of lead ore has been cut at 1100 ft. in the Tennessee mine at Chloride. A large flow of water followed this development. This property is operated by the Needles Mining & Smelting Co., a subsidiary of the United States Smelting, Refining & Mining Co., and ore is shipped to the smelter at Needles.

Yavapai County

The Arizona Copper-Gold Mining Co. has been reorganized, according to R. H. Burmeister. The claims are at Cherry creek. The Leghorn has been opened to 650 ft., showing mostly gold in the vein which averages two feet in width. A Lane mill has recovered $15 per ton. The main shaft is to be sunk to 2000 ft., and a mill and cyanide plant is contemplated.——There are several other properties in this district.

The Big Pine and Mascot companies have made an agreement for joint operation. The former's property on Senator mountain has been opened by 3000 ft. of adits and lateral work, proving a large tonnage of ore averaging $9.59 per ton. Additional ground was secured, and an adit will be driven about 4100 ft. and will open more ore and act as a means of transporting ore to the mill and cyanide plant to be moved from Harrington to Hassayampa creek. Equipment from the Mascot will be used.——Five mills in different parts of the county have been overhauled lately, and others are to be installed.

CALIFORNIA

Amador County

Coal from Ione is to be produced in marketable form by the National Briquetting Manufacturing Co., which is erecting a plant.

Butte County

Two boats of the Oroville Dredging Co. recovered $3781 during the week ended November 5.——The El Oro company's boat is now digging toward the main road out of Oroville, on the other side of which is the Gardella dredge.

Calaveras County

(Special Correspondence.)—The Royal mine at Hodson is being unwatered rapidly, a Starrett pump now lifting 1000 gal. per minute. The workings are estimated to contain 30,000,000 gal. As the mine contains a large tonnage of profitable ore, the draining is being watched with interest. The 120-stamp mill is ready for crushing.

The Womble property, on the south of the Royal, is at present being examined by San Francisco people. This is also a large low-grade property.——On the north of the Royal, the Mountain King owners are preparing to sink 200 ft. below the present depth of 600 ft., having recently cut a fine ore-shoot which extends from the surface to the said level.

Hodson, December 22.

Eldorado County

Nevada mining men have secured a lease of the Lukens company's mine near Pilot Hill. It is fully equipped.

Kern County

The Weringer Mines Co. has been incorporated with a capital of $500,000 to operate the Weringer Greenback copper mine at Woody, 25 miles from a railroad. The output to date is $40,000, and ore reserves are estimated at 4000 tons. So far the ore has returned from 8 to 33 per cent.

Nevada County

A rich shoot has been cut in the Pennsylvania by a crosscut driven at 3400 ft. from the Empire adjoining. The former is owned by the Empire company.——The You Bet Mining Co. has failed to make payments on the Jerry Goodwin and Nichols gravel claims at You Bet, and representatives of the latter estate have assumed control. Litigation is expected to follow this action.

Placer County

An extensive magnesite deposit near Auburn has been sold by J. H. Johnson and J. D. Sullivan to an Eastern syndicate.

Shasta County

The old Summit mine at French gulch is being reworked by E. J. Barnes and others of Redding. This property is between the Brunswick and Majara.——Nevada people have acquired the Clipper gold mine near Kennett, and power lines of the Northern California Power Co. are being erected from the Uncle Sam mine nearby.——A pocket in a claim recently bought by C. Bading and J. McBride near Kennett yielded $900 in gold last week.

Sierra County

(Special Correspondence.)—Options have been taken on the Russell placer holdings and a large area of contiguous territory by engineers said to represent Natomas Consolidated. Arrangements have been made to drill the ground, preliminary prospecting indicating rich gravel near the bedrock.

Redding, December 15.

Rich ore has been cut in the Keystone mine near Sierra City.——The Cleveland quartz mine has been sold to Eastern people who will start work in January, in charge of D. McGonigal.

Trinity County

It is reported that work at the Lagrange gravel mine, near Weaverville, has been curtailed considerably, and the superintendent of ditches and mine foreman's positions, held by L. P. Poage and P. Jensen, respectively, have been abolished.

TRINITY COUNTY, CALIFORNIA.

Tuolumne County

(Special Correspondence.)—The foundation for a 10-stamp mill is being constructed at the Mangante mine, near Jamestown. At present only five stamps will be installed. The machinery was purchased from a property above Columbia.——The Clio mine is being unwatered for inspection, with a view to the resumption of operations.——The old Mazeppa mine, near Stent, owned by J. F. Parr and others, will shortly be worked. The work planned will be done east of the present developed portion of the claim. Preparatory work was begun this week.——Articles of incorporation of the McAlpine Mines Co. were filed here this week. The Company, organized under the laws of California, has a capital of $1,500,000, the shares having a par value of $1 each. The Company owns the McAlpine group of four claims, situated in the southwestern part of the county. The directors of the new corporation are F. R. Whitcomb, C. L. LaRue, and M. C. Hassett, of San Francisco, A. L. Bernard, of San Anselmo, and Fannie W. McLean, of Berkeley.——Considerable new machinery has been purchased for the Blue Eagle mine, situated in the Jawbone district, and operated by an Oakland company. The property is in an isolated region, necessitating the transportation of the machinery on sleds and pack-animals. The heavier pieces were Burleigh drills, an air-compressor, and a gasoline engine, the latter weighing about 800 lb.——It is reported that work will at once be resumed at the Montezuma Tunnel gravel mine, on Table mountain. The property is owned by C. F. Montgomery of San Francisco.

Sonora, December 5.

COLORADO

Gilpin County

Increased activity is noticeable in the Hughesville district, which is an old silver producer. Lessees are reported to be getting fair results, and development at the Hope, Cracker Jack, Atlantic, and Alaska mines is encouraging. The Iron City concentrating plant below Black Hawk is treating from 60 to 75 tons of custom ore per day. The output in November was 33 cars of concentrate. William Crosley is in charge.——The Fagan mine is shipping ore to the Polar Star mill at Black Hawk.——A car of ore from a mine in Wyoming recently arrived at the Chamberlain sampling works at Black Hawk, and is being treated at the U. P. R. mill.——The Togo, in Willis gulch; Bnekeye, in Quartz valley; and Eureka are yielding good returns.

Lake County (Leadville)

(Special Correspondence.)—The Banker mine, which belongs to Mr. Rittenhouse, of Los Angeles, is to be unwatered and operated, according to latest information. This property has a shaft down 1100 ft., and has produced gold and zinc ores. The property is about 90 ft. distant from the Yak tunnel, with which it is proposed to connect it. It is stated that the property has a prospect of getting the extension of the Jonny vein, which is producing so much rich gold ore.

Boston, Massachusetts, December 11.

The Lake County Metal Mining Association met on December 12, but there were only 25 members present, which attendance the *Carbonate Chronicle* thinks shows that the movement is attracting little attention, and should have more interest taken in it.

Ouray County

The Ouray County Metal Mining Association held a meeting on December 14. There was a fair attendance. The society had a call from the Colorado Metal Mining Association to go to Denver on January 11.

On December 14 an explosion at the Wanakah smelter wrecked the flue and dust chamber, and injured two employees. The Company thinks this was the result of dynamite placed

by outsiders. The old furnace will be used while the new one is undergoing repair.

PARK COUNTY

The London mine is attracting increased attention from lessees, who have good chances in this property. A number of Leadville miners have blocks.

TELLER COUNTY (CRIPPLE CREEK)

An interim dividend, No. 9, of 5%, was paid by Stratton's Independence on December 10. In October the mill treated 9140 tons of ore, with a profit of $6279. The mine made a loss of $1327.——Four feet of $100 ore has been cut by Wilcox and partners in the Upper Granite mine on Bull hill.——Rich shoots of sylvanite ore have been exposed by recent work in the Vindicator. Installation of surface equipment proceeds steadily.——A large tonnage of good ore has been opened at 1700 ft. in the Portland.——At 100 ft. in the Orpha May, on Bull hill, 18 in. of ore assaying up to $81 per ton is being extracted by lessees.——Prominent business men of the district have formed a syndicate to prospect Gold hill and adjacent ground. The C. O. D. shaft is to be sunk from 800 to 1300 ft. ——Machinery is being erected on the Half Moon property on Gold hill.——Eighteen inches of rich smelting ore has been cut in the Ajax on Bull hill.——Next to the Cresson is the Gold Sovereign, and 6 ft. of $54 ore has been cut at 1050 ft. This is thought to be an extension of the rich Cresson shoot.

IDAHO

BONNER COUNTY

(Special Correspondence.)—The Idaho Gold & Radium Mining Co. has been developing its property at Lenia for four years, 40 to 50, mainly shareholders, being employed. Inclusion of 'Radium' in the Company's title does not mean that this element metal is to be produced, but the word is simply a distinguishing mark from other Idaho gold mining companies. The property consists of 800 acres of gravel, and 40 claims containing four gold-bearing veins. Assessment work only has been done on the latter, yet they are promising. A hydraulic plant is being installed, Boulder creek being the source of supply. A four-mile ditch, 27 ft. wide, will deliver 10,000 miner's inches under a head of 400 ft. A hydro-electric plant is also to be installed to use 200 ft. head, and will generate 2500 hp. for use on the property. The sluice-boxes will discharge gravel into a cañon 1000 ft. wide and about a mile long. The distance from camp to the Great Northern railroad is $1\frac{1}{2}$ miles, but to cover this distance at a uniform 4% grade it was necessary to construct 5 miles of auto-truck road. Two additional miles were also made leading to various works. Much of this road was cut through solid rock. Work on the ditch is well on toward completion. So far, the Company has spent $190,000.

Lenia, December 7.

OWYHEE COUNTY

(Special Correspondence.)—An effort is being made at Boston, Massachusetts, to finance the reopening of the Henrietta or Big I mine. This mine has a 30-stamp mill and has been opened by shaft and adit. It was discovered on a Sunday morning in 1876 by three old miners who stood talking on a bluff about eight miles northeast of Silver City. As the story goes, a little dog, belonging to one of the party, scratching at a rat or gopher hole uncovered a rich nugget of ore. It is claimed that some ore was sold at Silver City at $1 per pound, and these early shipments totaled $750,000. The plan is to mill the dump of about 40,000 tons, with estimated values of about $30 per ton.

Boston, December 11.

SHOSHONE COUNTY (COEUR D'ALENE)

At 900 ft. in the Hypotheek, 10 ft. of high-grade lead ore has been opened. A large pump has been ordered from Spokane. P. F. Rodgers is superintendent.——Hardinge mills are being installed in the Hunter mill. The Company employs from 125 to 150 men.——A large tonnage of ore has been developed in the Black Bear Consolidated. A mill is contemplated for next spring.——The Gertie adit, in Cañon creek, was driven 280 ft. in November, two shifts working. Two water Leyner drills are used. The adit will be driven a further 2900 ft. to cut the Gertie vein at 3600 ft.——In the suit of the Marsh Mining Co. *v.* the Washington Water Power Co., wherein the former lost its case in the matter of power rates, a rehearing is to be held on January 15.

MISSOURI

JASPER COUNTY

Ore output of the Missouri-Kansas-Oklahoma district for 50 weeks of this year is as follows: blende, 232,702 tons; calamine, 14,985 tons; and lead, 40,180 tons; with a total value of $11,197,971. Three Webb City mining companies sold 1200 tons of zinc ore for $62,000 to the American Metal Co. last week. Those concerned in the deal were the Century, 600 tons; Coahuila, 300 tons; and Oronogo Circle, 250 tons, the two former receiving $50, and the latter $49 per ton. The Company is said to be in the market for 10,000 tons in all.

MONTANA

MADISON COUNTY

Owing to a bolt coming loose in a controller, causing a short circuit, two men were electrocuted on No. 3 dredge of the Conrey Mining Co., near Ruby, on November 8. Leon Dusseault was winchman and received the shock through two control levers for the digging ladder and the shifting gear of the boat. J. J. Hagenach also came into contact with a lever when rendering assistance to the former employee.

POWELL COUNTY

The Elliston phosphate field is described in *Bulletin* 580-N of the U. S. Geological Survey by R. W. Stone and C. A. Bonine. They were assisted by J. E. Richardson, Jr. The deposit is two to seven miles of the Northern Pacific line. Owing to its recent discovery there has been no development, also as there is no market reasonably near to justify mining and reduction to a fertilizer. A total of 86,000,000 tons is estimated in the whole area, the thickness being four feet.

SILVERBOW COUNTY

A sectional spout for the flow of slag from blast-furnaces to settlers is used at the Washoe smelter, and Albert R. Blak is suing the Anaconda company for $50,000 for alleged infringement of the device. The plaintiff previously lost a similar case against a subsidiary of the Company.

NEVADA

ESMERALDA COUNTY

The Western Ore Purchasing Co. is overhauling its sampling plant at Goldfield, on account of recent developments in the district.

Through a deal made by C. O. Whittemore, of Los Angeles, and Charles S. Sprague, of the Jumbo Extension company, the Lone Star Consolidated has been financed for further development.——A 20-ton roller mill has been secured for the Gold Prince in the Gold Crater district east of Goldfield, by the manager, Charles Orr.——Work at 921 and 1017 ft. in the Jumbo Extension continues to open rich ore.

In spite of the present boom at Goldfield, there are 325 idle miners in the district, according to the Goldfield Consolidated company.——The Goldfield Consolidated output in November was 28,425 tons, yielding a net profit of $145,312. Costs totaled $6.62 per ton. Development totaled 2359 ft. at $6.08 per foot. No. 4 level of the Combination, 100 ft. northeast of the shaft, produced 447 tons of $25 ore. No. 1 level of the Mohawk yielded 545 tons of $20 ore.

HUMBOLDT COUNTY

A fine specimen has been extracted from the Nevada Packard mine at Rochester. It is an altered rhyolite weighing 140 lb., spotted with horn and ruby silver, and assaying 1500 oz., also $2.60 gold per ton.——L. A. Friedman of Lovelocks has purchased 150,000 shares in the Rochester Mines Co., also 600,000 in the Rochester Weaver Mining Co. Lessees in the Seven Troughs are doing well, according to the manager, C. W. Poole, and royalties received by the Company are from $1000 to $2000 per month.

LYON COUNTY

Cyanide plants at Silver City have been closed for the winter. The stamp-mills have been busy lately.

MINERAL COUNTY

The Lucky Boy adit, five miles from Hawthorne, is in 5100 ft., and indications point to the contact being near. Progress amounts to about 8 ft. daily. During the driving of this adit, four veins were cut, from which some rich ore has been shipped.

NYE COUNTY

Five mines at Tonopah produced 9001 tons of ore, valued at $187,978, during the week ended December 19.——In November, the Belmont treated 14,880 tons, yielding 348,835 oz. silver and 3825 oz. gold, with a profit of $135,532. Profits for 11 months total $1,490,027. The Jim Butler profit was $28,390 from 3087 tons. The Tonopah mill at Millers produced 249,150 oz. bullion, giving a profit of $72,400. Profits for 11 months total $1,010,713, but since the war started the monthly net returns have been very erratic. The dredges in Colorado add to this amount considerably.——The Extension mill is now treating 271 tons per day. The last bullion shipment was 28 bars, weighing 52,180 oz.——Development in the Montana last week amounted to 134 ft.——The Jim Butler-West End suit is making good progress. Judge Averill has been underground to see the area in dispute. Testimony for the West End is finished, and that for the Jim Butler may end by Christmas.——Development in the North Star at 1050 ft. is promising.——Energetic prospecting continues at Tonogold, but there is nothing important to chronicle.

Mining at the White Caps costs $1.35 per ton. The Manhattan Milling & Ore Co.'s 10-stamp mill and cyanide plant is now operated by the White Caps people.——The new mill at the Big Pine is working.——A heating system has been installed in the Associated mill, which will prevent a further freeze-up. There are 32 men employed in the mine and plant.

STOREY COUNTY

During the past financial year the Ophir Silver Mining Co. extracted $64,290 from 2248 tons of ore, 1738 tons of tailing, and 3087 tons of dump material, according to the superintendent, T. F. McCormick. His report covers work at 2000, 2350, 2400, and 2500 ft.——Another fire has started in the Comstock, this time at the 1500-ft. station of the joint Crown Point-Belcher incline in Gold hill. This shaft is used for pumping. Bulkheads have been built below the 1400 ft. station, and it is expected to soon get the outbreak under control.

The committee of northend mine superintendents consisting of William E. Sharon, Whitman Symmes, and Thomas F. McCormick, to whom was referred the matter of unwatering that portion of the Comstock lode an additional 200 ft. from the 2500 to the 2700-ft. level, have presented their report to William C. Ralston, president of the Comstock Pumping Association at San Francisco. They report that they have taken under consideration the use of the old winzes which run from the 2500 to the 2700-ft. level, and in this connection have considered their most available use for unwatering the mines and also for mining and ventilating purposes. They decided on a method which gives the best use of all the old winzes now accessible, the joint Ophir and Mexican winze to be used for pumping only, and the others to be used for mining and ventilation. It will be both feasible and more advantageous to locate the pumps for unwatering the 2700-ft. level in the old joint Ophir-Mexican winze which goes down from the 2500 to the 2900-ft. level. That winze was carefully sounded and apparently only 8 to 12 ft. of plank and other debris will have to be removed from near the 2700-ft. level in order to drain completely that level in the centre of the North End mines. In order to drain completely all of the North End mines on the 2700-ft. level, it probably will be necessary to install a small auxiliary pump in the Consolidated Virginia east winze on account of the grade in the connecting drift, but this, however, is unnecessary at present and has not been taken into consideration in this report. The installation of pumps in the joint Mexican and Ophir winze has the advantage that it will drain the ground that is now most urgently desired for exploration upon the 2700-ft. level, and in case it should be desirable in the future to reach the 2900-ft. level, this is the only winze that would be available to reach that point. Under this plan the Ophir, and, if thought desirable, the Consolidated Virginia, can work upon the 2700-ft. level through the old joint California and Ophir east winze, which runs from the 2500 to the 2700-ft. level. The Mexican, and, if thought desirable, the Union, can mine through the old joint Union and Mexican east winze that runs from the 2500 to the 2700-ft. level. The old joint Sierra Nevada and Union east winze from the 2500 to the 2900-ft. level will also be available for exploration in the Sierra Nevada and Union mines. The necessary pumps for this work are on hand, and a considerable amount of other material that is required. Additional material to the extent of about $4000 must be purchased to complete the pumping installation. The expense of installing the necessary pumps and of lowering the water to the 2700-ft. level, including the cost of power, is estimated at $6000 per month, and it will require three months' time to complete this work. This total of $22,000 covers everything which is possible to estimate at this time. It is advisable, however, to add $5000 more to that amount to cover unforeseen contingencies.

WHITE PINE COUNTY

Some notes on the copper ores at Ely, by Alfred R. Whitman, are given in the *Bulletin* of the department of geology of the University of California, of December 5. The writer studied the deposits in the summer of 1913. An abstract is given in another issue of this journal.

NEW MEXICO

GRANT COUNTY

There are 61 mining concerns in this county, as well as individual operators, and the total assessed valuation of the county is $20,660,067. Of this, the Chino Copper Co. amounts to $4,062,252. One-third of the valuation is subject to taxation. The total of taxes due on the 1914 assessment is $244,388, the Chino company contributing $43,409. The county last year taxed mine products, to which the Company objects, and a test case is being prepared to prove the right of the county to collect this tax, a suit of interest to all New Mexican mining companies.

SOUTH DAKOTA

LAWRENCE COUNTY

In *The Pahasapa Quarterly* of the South Dakota School of Mines, Victor Ziegler states that two minerals have to be added to those in his 'Minerals of the Black Hills.' These are sillimannite, an aluminum silicate, found near Custer; and pseudomalachite(?), a copper mineral found in certain pegmatites of the Keystone district.

Development in the Heidelberg has been good, and shipments of ore are to be resumed to the Golden Reward cyanide plant at Deadwood.——The Hidden Treasure has resumed

work in charge of Stewart Thompson.——The Homestake aid fund for employees has a cash balance of $39,557. Revenue in November was $3403.——A test run has been made on tin ore near Hill City by McNish and Mills. Work will be resumed in the spring.

TEXAS

Burnet County

(Special Correspondence.)—The Darling Mining Co. has been organized for the purpose of conducting extensive mining operations in Texas and Arkansas. Its principal office is in Galveston, the incorporators being J. E. Howard, T. A. Kindred, and T. D. Lufkin, all of that city. It is stated that the Company will open lead mines in the Burnet district, situated near the town of that name, also in Arkansas.

Austin, December 15.

UTAH

Juab County

Two developments have occurred in new ground of the Lower Mammoth at Tintic. At 700 ft. there is 4 ft. of ore assaying 27 oz. silver, $1 gold, and 1% copper; and at 1000 ft. is a shoot of 4 to 6% copper ore.

Salt Lake County

The report of the South Hecla Mining Co., George H. Watson, general manager, covers the year ended September 1. Development totaled 1190 ft., mostly on the Wedge vein. As far as opened, the orebody is 18 ft. wide. Work to date totals 17,928 ft. Ore sold amounted to 4118 tons, yielding $46,510 net. It contained 141 oz. gold, 85,618 oz. silver, 1,030,066 lb. lead, 586,867 lb. zinc, 1405 lb. copper, and 82,675 lb. iron. The surplus is $36,524. Until metal prices improve, a further curtailment of production is advised.

The Montana Bingham adit is in 3460 ft., and 700 ft. from the objective, the Cougar vein. More money is necessary to complete this work, which will yield revenue from other companies for ore transport and sale of water, and a 1c. assessment has been levied. Lessees are opening a vein cut about 450 ft. from the present face of the adit. The ore contains copper, silver, and gold.

Summit County

During 11 months of the current year the Park City district shipped 1475 cars of ore, equal to 64,541 tons, as follows: Silver King Coalition, 28,890; Daly-Judge, 32,665; Daly West, 3495; Silver King Consolidated, 7707; Mines Operating Co., 763; American Flag, 166; Charles Moore, 481; Coleman, 33; Daly Mining Co., 82; Thompson-Quincy, 240; Ontario Mining Co., 32; Glencoe, 103; and Little Bell, 76 tons.

The president of the Silver King Consolidated Mining Co. of Utah, Solon Spiro, has issued a circular to the shareholders containing the following information: All litigation between the Company and the Silver King Coalition Mines Co. is finally settled. There being some adjustment necessary regarding certain mining claims, the Consolidated 'quit-claimed' all rights to the Delaware, Vesuvius, Ladies Drum, and Mayflower to the Coalition, in exchange for deeds to the Andes and Custer claims, both of which are desirable acquisitions. Developments in the Consolidated mine have been excellent of late. Ore has been opened from near the shaft at 1500 ft. to 1700 ft. at the western boundary, a distance, measured diagonally, of about 1000 ft. Its width north and south is 375 ft. with ore in both ends. The upper and lower edges in the main vein 'bed' or flatten to 2 to 6 ft. wide, ore in the 'beddings' assaying 50 oz. silver, 27% lead, 0.05 oz. gold, and 1.13% copper. From wall to wall the ore is uniform in value. Of 502 mine cars of ore hoisted in the first 10 days of November, only two were rated as second-class. Rises and drifts are further opening the shoot, which contains a large tonnage of ore. On account of the low price of lead and silver, only the ore extracted in development is being marketed; but 100 tons of smelting ore could easily be shipped daily. Under the management of Harry A. Lee the mine was opened, and new machinery erected. The latter includes a 10,000-ft. water pipe, a two-stage motor-driven Allis-Chalmers air-compressor of 2600-cu. ft. capacity, new bunk-houses, sanitary system, and mine telephones. The president commends the work done by the manager; the surveyor and assayer, Norman N. Blye; master mechanic, Lee Hernon; shift-bosses, S. Prudence and Lee Glockner; chief timberman, Julius Lee; time-keeper and boarding-house manager, W. H. Middaugh, and a score of faithful miners. Co-operation and harmonious relationship has been excellent. The Company will pay a dividend of 10c. per share on December 31.

CANADA

British Columbia

Dividends paid by the principal mining companies of the province in 1914 are estimated as follows: Consolidated Mining & Smelting, $464,352; Granby, $449,955; Hedley, $360,000; and Standard, $475,000; a total of $1,749,307. The war has affected the metal companies considerably.

Four blast-furnaces are now running at Grand Forks, with a corresponding increase in mining at Phoenix.

Ontario

The Dome mine yielded $96,771 from 22,040 tons of ore in November, giving an average of $4.39 per ton.——On No. 1 vein at 800 ft. in the Hollinger, two faces are being opened with good indications. A 3% dividend will be paid on December 30, making 36% for the year and 87% to date, equal to $2,610,000.

Silver shipments from Cobalt during the week ended December 12 totaled 398,153 oz., valued at $197,346.——The Trethewey mine's output in November was 40,080 oz. from 3100 tons of ore assaying 16.5 oz. per ton.——The Buffalo Mines, Ltd., states that development since August has been satisfactory. The plant is to be worked at full capacity; but it is intended to store concentrate for the present.

COLOMBIA

The Pato dredge recovered $32,500 from 52,000 cu. yd. of gravel during the two weeks ended November 24.

MEXICO

An advertisement in the *Globe*, Toronto, Canada, is to the effect that the Mexican Light & Power Co., Ltd., will default on payment of the half-yearly interest coupon due December 1 on the $9,733,333 of 5% second mortgage 50-year bonds, owing to the conditions that prevail in Mexico.

Hidalgo

The Santa Gertrudis Co. reports as follows for the third quarter of 1914: Operations continued unmolested. The interior counter shaft was sunk 9 ft. to 230 ft. below No. 20 level, when work was suspended. In the upper portion of the mine 718 ft. of work was accomplished, of which 339 ft. was in average low-grade, profitable ore. On No. 13 level, the hanging-wall shoot, lying between the North and No. 8 veins, was opened to a length of 60 ft. and width of 30 ft., averaging $7.20 per ton. Development generally was confined to ore already located; a shortage of dynamite, since overcome, made other work inadvisable. The mill restarted on July 6, and by the end of the quarter was at 85% capacity. Until regular supplies of cyanide can be secured, and Mexican and European conditions bettered, it is not intended to increase production. This was $336,000 from 66,634 tons of ore. The net profit was $97,000. The profit in October was $58,000.

Tamaulipas

According to vice-consul Thomas H. Bevan, writing on November 3, the attention of the oil men around Tampico during October centred on the great fight of the Eagle Oil Co. to extinguish the Portrero del Llano fire. This well is said

to be the largest in the world, its estimated production being 150,000 bbl. per day. Steam and chemicals have so far failed to put out the fire, and the Company is now digging an adit up to the well and will attempt to cut off the flow from beneath the ground. The same Company has just successfully capped its Naranjos well No. 1, which broke loose during the early part of October and flowed at the rate of 45,000 bbl. per day down the Tancochin river for two weeks. The river was covered with a heavy coating of oil for a distance of 25 miles to its mouth in Lake Tamiahua. It has been estimated that 500,000 bbl. of oil was lost before the well was recapped. The movement of crude oil out of Tampico during October shows a considerable decrease compared with the same month of the preceding year. During October, 1913, 1,032,706 bbl. was shipped to the United States, while during October of this year 886,245 bbl. was exported.

NICARAGUA

According to A. Busher in *The American* at Bluefields, conditions in the Pis Pis district are bad, although there are indications of increased activity. The large number of options granted have not helped the country much, as no sales have been concluded.—At the Lone Star, work has continued as usual. Slime from the mill is being saved, and a plant for its treatment is contemplated. Norman McInnes is owner.——Owing to the Grenfell failure in England and the war, it is

SIEMPRE VIVA FALLS, IN THE PIS PIS DISTRICT, NICARAGUA. THEY ARE 98 FT. WIDE AND 102 FT. HIGH, AND THE FLOW OF WATER IS SUFFICIENT TO GENERATE 100,000 HORSE-POWER.

reported that the options on the Bonanza, Siempre Viva, Lone Star, and Mars have been given up. Most of the staff left the Bonanza several months ago. The Mars and Siempre Viva mines are closed, but the latter's hydro-electric plant is supplying power for the Concordia mine, in charge of Paul Reuer. ——The old Constantia is being reopened by R. A. O'Brien. ——Developments in the Experiencia are promising. A 3-stamp mill is to be worked.——The Tonopah Mining Co. of Nevada is actively opening the Panama mine, in charge of Louis Garbrecht. Results are considered good.——The Tunky Mining Co. is exploiting its claims near the Panama and Bonanza.——The Deitrick concession has been ordered canceled ——The police department seems to have collapsed, as every *mozo* carries a gun and murders are becoming more frequent. *Aguardiente*, a liquor, is being made at many *fincas* and sold at the mines, where the only effort is made to stop its sale. Most of the men are quiet, but a few should be removed. It is hoped that better conditions as to policing may be brought about soon.

PERSONAL

C. Colcock Jones is in southern Utah.

A. A. Blow was in New York last week.

Webb Smith was in San Francisco Monday.

C. W. Merrill has returned from New York.

H. M. Stronck is in California for the winter.

E. W. Keith was in San Francisco Wednesday.

James W. Neill was in San Francisco last week.

B. P. Thayer has returned to New York from Butte.

L. D. Ricketts has returned to New York from Arizona.

F. W. Bradley expects to return to San Francisco next week.

Thomas H. Leggett has returned to New York from California.

Ernest Stein is with the Rosario Mining & Milling Co. at Durango, Mexico.

T. A. Rickard is serving as a special constable guarding bridges, etc., in England.

The Geological Society of America will hold its twenty-seventh annual meeting at Philadelphia on December 29 to 31.

Ralph Arnold was in New York last week, returning from Venezuela, and is on his way to California.

A. L. Hurley, of the Daly-Judge Mining Co., has been appointed superintendent of the Cardiff mine, near Park City, Utah.

Theo. Denis, being a French born subject, has received notice to hold himself in readiness for recall from Quebec to his native land.

N. O. Lawton, mining and consulting engineer of Lawton, Michigan, has gone to Hurly, Wisconsin, where he will be engaged in special work for the Montreal Mining Co. until about January 1, 1915.

Officers of the Royal Gold Mines Co., operating the old mine at Hodson, Calaveras county, are as follows: Managing director, F. W. Page; assistant manager, H. W. Condar; and underground superintendent, W. H. Clary.

Robeson T. White, manager for the Caucasus Copper Co., near Batum, Russia, was wounded by Turkish troops in an attack on the property on December 17, according to reports from Petrograd. Two members of his staff were taken prisoners, but one of them, an American, has been released.

SCHOOLS AND SOCIETIES

The Illuminating Engineering Society, Chicago branch, met on December 18.

The Colorado School of Mines, at Golden, will start a short course for prospectors on February 8, 1915. No fees will be charged save a nominal sum to cover supplies used.

The American Electrochemical Society met in New York on December 11. The Pittsburgh section met on the previous day. The spring meeting will be held in Atlantic City on April 22, 23, 24, 1915.

The University of California has issued its *Register* for 1913-14, with announcements for 1914-15. The publication consists of 875 pages and contains everything connected with the work of the institution.

THE MARKET PLACE

Weekly Summary of Prices of Shares and Metals

Metal Prices

San Francisco, December 21.

Antimony	15 —15¾
Electrolytic copper	14 —14½
Pig lead	4.05— 5.00
Quicksilver (flask)	$53.00
Spelter	6½— 6¾
Tin	34½—36
Zinc dust, 100-kg. zinc-lined cases	9

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, December 24.—Copper is quiet and weaker, lead is dull, and spelter weaker. Phelps, Dodge & Co. has declared another dividend, making $14 per share, against $16.50 in 1913.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

Date.		Average week ending	
Dec. 17	49.50	Dec. 2	49 33

June	59.03	56.13	Dec.	57.73	....

The tendency of prices has been weaker. Samuel Montagu & Co., of London, stated on December 3 that the amount of supplies has been limited, and this fact really governed prices, rather than urgency of demand from any particular quarter. In so narrow a market, comparatively small orders are sufficient to affect prices. The stock of bars in Bombay, India, increased from 3800 to 4000.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

The price of copper was lifted upward at a steady rate last week until the cables brought the news that the German fleet had sallied out and attacked towns on the coast of England. The possibility that shipping might be disarranged had its immediate effect in decreased foreign orders, and domestic buying as usual fell off at the same time. Probably confidence will gradually be restored unless there is more news of the activity of the German fleet. There is little change in regard to the ability to ship copper for export, except that the British government has ordered the release of the copper shipped on the 'Tellus,' which is detained at Gibraltar. This may have some effect in reassuring the Italian lines, which have been unwilling to accept copper shipments ever since the wholesale seizure of copper consigned to Italy. The Department of State has inquired of the British government as to what its attitude is in regard to the embargo placed on the exportation of copper by the Italian government, but so far no reply has been received. It is reported that altogether about 20,000,000 lb. of copper has been held up at Gibraltar. One of the prominent Italian copper dealers has come to this country to see what can be done in regard to getting the metal through to Italy, and has been in consultation with the Italian embassy at Washington. Producers here evidently expect a rising market for copper, as the sheet copper manufacturers have increased their base price to 18½c. for sheets and 16½c. for rolls. A month ago the price was 16½ and 14½c., respectively; the advance is a notable one. Of course the increased demand in war orders has been mostly felt by the brass trade since the war does not give rise to any increased demand for wire.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb, are given below:

Week ending

The tin situation is quiet. Arrivals in 17 days totaled 565 tons, while 2510 tons is afloat due up to December 28. Shipments from the Straits Settlements to England have been on a larger scale than of late

COMPANY REPORTS

AMALGAMATED ZINC (DE BAVAY'S), LTD.

The report of this Company, which buys zinc tailing at Broken Hill and treats it by flotation methods, covers the six months ended June 30, 1914. From the treatment of 247,386 tons the yield was 69,918 tons of concentrate assaying 48.6% zinc, 6.1% lead, and 8.9 oz. silver; also 687 tons of lead concentrate assaying 53.5% lead, 14.1% zinc, and 53.1 oz. silver. The profit was $290,000. Dividends of 25c. per share each were paid in February and May, making a total to date of $2,260,000. Owing to the war, contracts for the sale of concentrate were suspended, and a dividend of 25c. on August 12 was withheld. The reserve for depreciation is $240,000, and surplus $490,000.

CORNWALL TAILINGS COMPANY, LTD.

This is a concern financed by Australians to treat old dumps of tailing at the Carn Brea and Tincroft mines, near Redruth, Cornwall, containing about 1,000,000 tons. The plant consists of four tube-mills and concentrators, the product being smelted. During the year ended February 28, 1914, 113,116 tons of tailing yielded 370 tons of black tin. In the previous term there was 78,885 tons treated. The net profit was £3749, against £15,836, the decrease being due to the low price for the metal. Two dividends of 5s. per share, on 50,000 shares, were paid. Costs decreased from 4s. 6.5d. ($1.09) to 3s. 6d. (84c.) per ton of tailing treated. In September 1914 this was further reduced to 72c. per ton. Owing to the financial condition, tests for a better recovery have been suspended.

YUANMI GOLD MINES, LTD.

This Company operates the Yuanmi and Oroya Black Range mines in the East Murchison goldfield, Western Australia, and the report is for the year ended June 30, 1914. The general managers are Bewick, Moreing & Co., and consulting engineers, James Bros., the superintendent being H. G. Walton.

In the Yuanmi property, development totaled 4747 ft. at a cost of $1 per ton of ore milled. The main shaft is 519 ft. deep. The principal objective of the work done has been the delimitation and further opening of the known orebodies at four levels, and the shaft was sunk 68 ft., preparatory to proving the mine on No. 5 level. Ore reserves are estimated as 9235 tons of oxide ore worth $7.54 per ton, and 29,635 tons of sulphide ore assaying $9.70 per ton. The total is equal to eight months' supply for the mill.

Work in the Oroya Black Range mine amounted to 2527 ft., costing 70c. per ton milled. The most important work was sinking a winze 263 ft. to 548 ft. depth.

Results from the two mines are as follows:

Details of operation.	Yuanmi.	Oroya Black Range.
Stamps working on oxide ore	20	20
Krupp ball-mill for sulphide ore	one No. 8	.....
Ore crushed, tons	59,094	54,460
Yield, fine ounces	22,037	20,653
Revenue from gold, slag, etc.	$451,000	$423,000
Joint revenue	$874,000	
Expenditure	710,000	
Depreciation	106,000	
Profit	58,000	
Credit of profit and loss account	97,000	
Dividend of 24c. per share	84,000	

Buildings, plants, stores, etc., are valued at about $240,000, and cash $67,000. Details of costs will be given in another issue of the *Press*. On page 1002 appear some notes on treatment at the Yuanmi mill.

Analysis of Coal with Phenol as a Solvent. By S. W. Parr and H. F. Hadley. *Bulletin* 76. P. 41. Illustrated. This bulletin shows that by means of phenol, bituminous coal may be divided into two main portions. A study of each division can therefore be carried on to much better advantage than when in the combined state. In general it has been found that the resinic or pitch-like material is soluble in phenol, that it possesses substantially all of the coke producing ingredients, that oxidation destroys the coking property, that this oxidation occurs slowly at ordinary temperatures and proceeds much more rapidly at 212 F. The insoluble material or cellulose residuum is a more active absorber of oxygen; it has no coking property but resembles the lignitic coals in this respect as also in its avidity for oxygen. It is, therefore, to be considered as the constituent most actively involved in spontaneous combustion, deterioration, and other difficulties attending the storage of coal.

New Machines and Devices

Double-Deck Deister Tables

The Deister Machine Co.'s double-deck sand table consists of two rhomboidal shaped decks, one mounted above the other as shown in the halftone. The two decks are bound rigidly together and inclined at right angles to and slightly in the line of motion. The decks are covered with linoleum and riffled practically over the entire surface, the riffles running the full length of the decks in line with the motion. It is claimed that the patented duplex plateau type of riffle along the mineral discharge edge not only makes possible the final separation and cleaning of the concentrates, but also doubles the capacity of the machine. The average height of the riffles is one-quarter inch and they are in most cases spaced only one-inch centres. The decks are constructed of cypress timber, all fastenings being either screws or bolts and rigidly tied wherever the peculiar strains to which a table deck is subjected require it. The decks may be made sectionalized for muleback transportation. The shipping weight of the table is about 2000 lb. The capacity of the table is said to be from 60 to 150 tons per 24 hours when making a finished product, depending upon the character of the ore, the mesh, and the treatment to which the ore has been previously subjected. The amount of wash water varies with the character of the ore to be treated, and is said to be from 4 to 6 gal. per minute per deck, and $\frac{3}{4}$ hp. is ample for each machine. Under average conditions a uniform speed of 215 r.p.m. and a stroke of $1\frac{1}{16}$ in. is recommended. The machine is especially adapted to the treatment of classified feeds ranging from 8 to 100 mesh and unclassified feeds.

DOUBLE-DECK TABLE.

The double-deck slime table manufactured by this Company has a capacity of from 10 to 25 tons per 24 hours, depending upon the character of the feed.

The Deister company has recently been awarded the contract for 112 tables to be used in the new mill of the Inspiration Copper Co. These tables are of the double-deck type and will be manufactured and delivered at the Company's property with the greatest possible haste. The present order is for one-half of the milling equipment, and the other half of the mill, it is expected, will be specified for shortly.

Commercial Paragraphs

Williams Bros., Ithaca, N. Y., has issued a circular entitled 'Well Drilling Machinery and Tools.' Williams drills are manufactured in a large variety to meet the requirements of practice and may be driven by steam or horse-power.

C. L. Berger & Sons, Boston, Mass., has for distribution illustrated reprints of extracts from the *Engineering Record* entitled 'Two Hundred Twelve Shots in One Hour.' This record for fast work in topographical surveys was made with a C. L. Berger & Sons transit.

The *Western Electric News*, which is a house organ of the Western Electric Co., for December contains an interesting illustrated article on telephone construction work on the Isthmus of Panama. The present position of the Company's European branches is also summarized.

Wood Drill Works, Paterson, N. J. Wear and tear upon drills has possibly been greater than upon any other tool, and therefore anything that increases its durability is most desirable. To increase the life of the Wood drill, the Company decided to change the construction of the cylinder chest and air head of the drill from ordinary cast iron to vanadium tungsten iron, which it is claimed adds very materially to the life of the drill. A recent catalogue of the Company describes in detail the construction and operation of the drills manufactured by this Company.

The American Boiler Life Co., Boston, Mass., is distributing an interesting pamphlet entitled 'Steam Boilers and Boiler Feed Water.' It is known that if certain of the natural elements found in waters exist to the extent of only 15 grains to the gallon, they will form over 600 lb. of solid rock scale in a 100-hp. boiler continually working at capacity for 30 days time. Experiments have proved that it takes heat as long to be transmitted through 0.1-in. layer of grease, oil, or 1-in. coating of scale, as through a 10-in. plate of steel. The influence that this will have upon the coal consumption and efficiency of the boiler is at once apparent. The booklet is devoted to a scientific discussion of boiler feed water and contains considerable data on the subject.

Mesta Machine Co., Pittsburgh, Pa., in Bulletin N discusses the air-compressors and vacuum-pumps manufactured by this Company. Piston speeds in excess of 500 ft. per minute have usually resulted in excessive wear and other troubles. By the use of the plate valves (Iversen patent), it is claimed that it is possible to make use of a much higher speed: in fact, the piston speed is limited only by the driving engine. The bulletin is devoted to a general discussion of compressors and vacuum-pumps and contains a discussion on the subject of efficiency. Bulletin K of the same Company is devoted to the subject of gears. The Company manufactures a large variety of gears, including the herringbone and other types, which are here illustrated and described.
